WIENER MEASURE IN A SPACE OF FUNCTIONS OF TWO VARIABLES⁽¹⁾

BY
J. YEH

1. Introduction. The Wiener space C_2 of functions of two variables is the collection of continuous functions $\{x(t, \tau)\}$ on the unit square $0 \leq t, \tau \leq 1$ satisfying $x(0, \tau) = x(t, 0) = 0$. Integration on this space was first introduced by T. Kitagawa in his *Analysis of variance applied to function spaces* [2]. There he defined the Wiener integral for functionals on C_2 of the type $H(x(t_1, \tau_1), \dots, x(t_r, \tau_s))$ where $H(\eta_{11}, \dots, \eta_{rs})$ is a function of rs real variables $\{\eta_{hk}\}$ ($h = 1, 2, \dots, r, k = 1, 2, \dots, s$) and $\{t_h\}, \{\tau_k\}$ are preassigned division points of the unit intervals $0 \leq t \leq 1, 0 \leq \tau \leq 1$ satisfying $0 = t_0 \leq t_1 \leq \dots \leq t_r \leq t_{r+1} = 1, 0 = \tau_0 \leq \tau_1 \leq \dots \leq \tau_s \leq \tau_{s+1} = 1$. The Wiener integral for this class of functionals was defined to be

$$\begin{aligned} \int_{C_2}^w H(x(t_1, \tau_1), \dots, x(t_r, \tau_s)) d_w x \\ = \int_{-\infty}^{\infty} \dots \int_{-\infty}^{\infty} H(\eta_{11}, \dots, \eta_{rs}) \prod_{h=1}^r \prod_{k=1}^s p(\Delta_{h,k}) d\eta_{11} \dots d\eta_{r,s} \end{aligned}$$

where

$$\begin{aligned} p(\Delta_{h,k}) &= \frac{1}{[\pi(t_h - t_{h-1})(\tau_k - \tau_{k-1})]^{1/2}} \\ &\cdot \exp \left\{ \frac{-(\eta_{h,k} - \eta_{h,k-1} - \eta_{h-1,k} + \eta_{h-1,k-1})^2}{(t_h - t_{h-1})(\tau_k - \tau_{k-1})} \right\}. \end{aligned}$$

He gave no proof that this definition of Wiener integral could be extended to more general functionals or that it had the properties of a Lebesgue integral.

It is the purpose of the present paper to define an interval class (or semi-algebra) of subsets of the C_2 space, a set function on this interval class and then prove that this set function is indeed a measure defined on the interval class. Once this is accomplished the measure can be extended to a measure on the Carathéodory extension of the interval class in the usual way. With this Carathéodory extension measurable functionals on C_2 may be defined

Received by the editors May 11, 1959.

⁽¹⁾ The present proof for the countable additivity of the Wiener measure is a generalization of an unpublished proof for the one-dimensional case given in lecture notes by R. H. Cameron. The author wishes to thank Professor Cameron for his advice in the writing of this paper.

and their integration on C_2 may be considered. This not only makes integration of more general functions than those in [2] possible but it also puts the subject on a firm logical foundation instead of mere optimism.

The definitions of the interval class and the Wiener measure are given by (2.1), (2.2), (2.3).

2. Definition of Wiener measure for C_2 . For the convenience we shall use different notations from those in [2]. Each element of C_2 will be written $f(x, y)$. Then C_2 is the collection of real valued continuous functions $f(x, y)$ on the domain $0 \leq x, y \leq 1$ satisfying $f(0, y) = f(x, 0) = 0$. A pair of real numbers (x, y) with $0 \leq x, y \leq 1$ is made to correspond to a point in the unit square of the xy -plane in the usual way. If P is a point in this square with coordinates (x, y) , we will write $f(P)$ for $f(x, y)$.

A class $\mathcal{g}$ of subsets of a space S is called an interval class if the following three conditions are satisfied:

1. If $I_1, I_2 \in \mathcal{g}$, then $I_1 \cap I_2 \in \mathcal{g}$.
2. $\emptyset, S \in \mathcal{g}$.
3. If $I \in \mathcal{g}$, then there exists a finite sequence of elements of $\mathcal{g}$, $I_0, I_1, \dots, I_n$ such that $I = I_0 \subset I_1 \subset \dots \subset I_n = S$ and $I_j - I_{j-1} \in \mathcal{g}$ ($n = 1, 2, \dots, n$).

A nonempty class $\mathcal{F}$ of subsets of a space S is called a field of sets if the union of any two elements of $\mathcal{F}$ and the complement of every element of $\mathcal{F}$ are also elements of $\mathcal{F}$. If further the union of any countable collection of elements of $\mathcal{F}$ belongs to $\mathcal{F}$ then $\mathcal{F}$ is called a Borel field of sets. In particular a field of sets is an interval class.

An extended positive valued set function $m(I)$ on an interval class $\mathcal{g}$ is called a measure if it is countably additive and $m(\emptyset) = 0$. Here by the extended positive number system we mean all the non-negative numbers and $+\infty$.

To define an interval class $\mathcal{g}$ of subsets of C_2 , let two finite sequences of numbers $0 = x_0 < x_1 < \dots < x_m \leq 1$, $0 = y_0 < y_1 < \dots < y_n \leq 1$ and a Lebesgue measurable set E of the mn -dimensional Euclidean space R_{mn} be given. Let a subset I of C_2 corresponding to the two sequences and the measurable set E be defined by

$$(2.1) \quad I\{x_1, \dots, x_m, y_1, \dots, y_n, E\} \\ = \{f \in C_2; [f(x_1, y_1), \dots, f(x_m, y_n)] \in E\}.$$

The mn points in the unit square, $(x_1, y_1), \dots, (x_m, y_n)$, and the set E will be called restriction points and restricting set of the set I . For a given collection of mn restriction points and a given restricting set a subset I of C_2 is uniquely determined by (2.1), but the converse is not true. For instance for the subset I defined by (2.1) we may throw in a few more partition points in the intervals $0 \leq x \leq 1$, $0 \leq y \leq 1$, so that there are p and q additional partition points on the unit x -interval and the unit y -interval respectively; let the restriction at each of the additional restriction points (x_i, y_i) be the trivial

restriction $-\infty < f(x_i, y_j) < +\infty$ and let the restriction set be $E \otimes R_{pn+qm+pq}$, a Lebesgue measurable set in $R_{(m+p)(n+q)}$. The subset of C_2 defined with the $(m+p)(n+q)$ restriction points and the restricting set $R_{(m+p)(n+q)}$ is identical with the one defined by (2.1).

Now let $\mathcal{J}$ be the collection of subsets of C_2 of the type (2.1). To show that $\mathcal{J}$ is an interval class, or even more that $\mathcal{J}$ is a field of sets, we observe the following. When we have two sets $I_1\{x_{11}, \dots, x_{1,m_1}, y_{11}, \dots, y_{1,n_1}, E_1\}$ and $I_2\{x_{21}, \dots, x_{2,m_2}, y_{21}, \dots, y_{2,n_2}, E_2\}$ we can make them comparable in terms of their restricting sets by using the Cartesian product of the partition points $\{x_{11}, \dots, x_{1,m_1}\} \cup \{x_{21}, \dots, x_{2,m_2}\}$ and $\{y_{11}, \dots, y_{1,n_1}\} \cup \{y_{21}, \dots, y_{2,n_2}\}$ as their restriction points by means of adding trivial restriction at each newly introduced restriction point and extending their restriction sets to two Lebesgue measurable sets E'_1 and E'_2 of the same Euclidean space. Then in comparing I_1 and I_2 we only have to compare E'_1 and E'_2 . This procedure can be generalized for any finite collection of sets $I_1, I_2, \dots, I_l$. If restricting sets $E_1, E_2, \dots, E_l$ are extended by the above procedure to $E'_1, E'_2, \dots, E'_l$ all in the same Euclidean space then $I_3 = I_1 \cup I_2$ if and only if $E'_3 = E'_1 \cup E'_2$, $I_2 = (I_1)^c$ if and only if $E'_2 = (E'_1)^c$ and $I_3 = I_1 \cap I_2$ if and only if $E'_3 = E'_1 \cap E'_2$. From the first two of the above three propositions and from the fact that the collection of Lebesgue measurable sets is a Borel field of sets, it follows that $\mathcal{J}$ is a field of sets and in particular an interval class.

Now if an interval $I \in \mathcal{J}$ is defined by (2.1), then $m(I)$ is given by

$$(2.2) \quad m(I) = \int_E (mn) \int W\{x_1, \dots, x_m, y_1, \dots, y_n\} du_{11} \dots du_{mn}$$

where

$$(2.3) \quad W\{x_1, \dots, x_m, y_1, \dots, y_n\} = \frac{1}{\{\pi^{mn} [x_1(x_2 - x_1) \dots (x_m - x_{m-1})]^n [y_1(y_2 - y_1) \dots (y_n - y_{n-1})]^m\}^{1/2}} \cdot \exp \left\{ - \sum_{i=1}^m \sum_{j=1}^n \frac{[u_{ij} - u_{i,j-1} - u_{i-1,j} + u_{i-1,j-1}]^2}{(x_i - x_{i-1})(y_j - y_{j-1})} \right\}$$

with the understanding that $u_{0,j} = u_{i,0} = 0$. Now in view of the fact that $m(I)$ for the interval I as given by (2.1) is defined by means of the restriction points and the restricting set that appear in (2.1) and that the expression of an interval by restriction points and restricting set is not unique, it is necessary to prove the independence of the value $m(I)$ from the choice of restriction points and restricting set of I . This is done in §3.

3. Uniqueness of the definition of the set function $m(I)$. To prove the uniqueness of the definition of $m(I)$ we show that when a finite number of partition points of the intervals $0 \leq x \leq 1$, $0 \leq y \leq 1$ are added and trivial re-

restrictions are added at the additional restriction points, the value of $m(I)$ remains unchanged. It suffices to consider, for instance, the introduction of an additional partition point ξ satisfying $x_{k-1} < \xi < x_k$ together with trivial restrictions at $(\xi, y_1), \dots, (\xi, y_n)$. With the partition points $x_1, \dots, x_{k-1}, \xi, x_k, \dots, x_m$ and $y_1, \dots, y_n$, $m(I)$ is given according to (2.2), (2.3), by

$$(3.1) \quad m(I) = \int (mn) \int_E W\{x_1, \dots, x_m, y_1, \dots, y_n\} \\ \cdot K\{x_{k-1}, \xi, x_k, y_1, \dots, y_n\} du_{11}, \dots, du_{m,n}$$

where

$$(3.2) \quad K\{x_{k-1}, \xi, x_k, y_1, \dots, y_n\} \\ = \frac{(x_k - x_{k-1})^{n/2}}{\pi^{n/2} [(\xi - x_{k-1})(x_k - \xi)]^{n/2} [y_1(y_2 - y_1) \dots (y_n - y_{n-1})]^{1/2}} \\ \cdot \int_{-\infty}^{\infty} (n) \int_{-\infty}^{\infty} \exp \left\{ \sum_{j=1}^n \left[-\frac{(u_{k,j} - u_{k,j-1} - v_j + v_{j-1})^2}{(x_k - \xi)(y_j - y_{j-1})} \right. \right. \\ \left. \left. - \frac{(v_j - v_{j-1} - u_{k-1,j} + u_{k-1,j-1})^2}{(\xi - x_{k-1})(y_j - y_{j-1})} \right. \right. \\ \left. \left. + \frac{(u_{k,j} - u_{k,j-1} - u_{k-1,j} + u_{k-1,j-1})^2}{(x_k - x_{k-1})(y_j - y_{j-1})} \right] \right\} dv_1 \dots dv_n.$$

Thus, for the uniqueness of $m(I)$ we only have to show that

$$K\{x_{k-1}, \xi, x_k, y_1, \dots, y_n\} = 1.$$

In evaluating K if we let $w_1 = v_1$, $w_2 = v_2 - v_1$, $\dots$, $w_n = v_n - v_{n-1}$, then the integral in the right hand of (3.2) becomes

$$(3.3) \quad \exp \left\{ \sum_{j=1}^n \frac{(u_{k,j} - u_{k,j-1} - u_{k-1,j} + u_{k-1,j-1})^2}{(x_k - x_{k-1})(y_j - y_{j-1})} \right\} \\ \cdot \prod_{j=1}^n \left[\int_{-\infty}^{\infty} \exp \left\{ -\frac{(u_{k,j} - u_{k,j-1} - w_j)^2}{(x_k - \xi)(y_j - y_{j-1})} \right. \right. \\ \left. \left. - \frac{(w_j - u_{k-1,j} + u_{k-1,j-1})^2}{(\xi - x_{k-1})(y_j - y_{j-1})} \right\} dw_j \right].$$

For the integrands in (3.3) we write

$$(3.4) \quad \frac{(u_{k,j} - u_{k,j-1} - w_j)^2}{(x_k - \xi)(y_j - y_{j-1})} + \frac{(w_j - u_{k-1,j} + u_{k-1,j-1})^2}{(\xi - x_{k-1})(y_j - y_{j-1})} \\ = Aw_j^2 + 2Bw_j + C = A \left(w_j + \frac{B}{A} \right)^2 + \left(C - \frac{B^2}{A} \right)$$

where

$$(3.5) \quad \begin{aligned} A &= \frac{x_k - x_{k-1}}{(x_k - \xi)(\xi - x_{k-1})(y_j - y_{j-1})}, \\ B &= \frac{-u_{k-1,j} + u_{k-1,j-1}}{(\xi - x_{k-1})(y_j - y_{j-1})} - \frac{u_{k,j} - u_{k,j-1}}{(x_k - \xi)(y_j - y_{j-1})}, \end{aligned}$$

and

$$C = \frac{(u_{k,j} - u_{k,j-1})^2}{(x_k - \xi)(y_j - y_{j-1})} + \frac{(-u_{k-1,j} + u_{k-1,j-1})^2}{(\xi - x_{k-1})(y_j - y_{j-1})},$$

and hence

$$(3.6) \quad C - \frac{B^2}{A} = \frac{(u_{k,j} - u_{k,j-1} - u_{k-1,j} + u_{k-1,j-1})^2}{(x_k - x_{k-1})(y_j - y_{j-1})}.$$

With (3.4), (3.6), each of the n integrals in (3.3) becomes

$$(3.7) \quad \exp \left\{ -\frac{(u_{k,j} - u_{k,j-1} - u_{k-1,j} + u_{k-1,j-1})^2}{(x_k - x_{k-1})(y_j - y_{j-1})} \right\} \cdot \int_{-\infty}^{\infty} \exp \left\{ -A \left(w_j + \frac{B}{A} \right)^2 \right\} dw_j$$

and finally with (3.5),

$$(3.8) \quad \begin{aligned} \int_{-\infty}^{\infty} \exp \left\{ -A \left(w_j - \frac{B}{A} \right)^2 \right\} dw_j \\ = \left(\frac{\pi}{A} \right)^{1/2} = \left[\frac{\pi(x_k - \xi)(\xi - x_{k-1})(y_j - y_{j-1})}{x_k - x_{k-1}} \right]^{1/2}. \end{aligned}$$

By (3.2), (3.3), (3.7), (3.8) it is seen readily that $K\{x_{k-1}, \xi, x_k, y_1, \dots, y_n\} = 1$ and the uniqueness of the definition of $m(I)$ is established.

4. Properties of $m(I)$. From (2.2), (2.3), the value of $m(I)$ is non-negative for any $I \in \mathcal{g}$. We point out here that $m(\emptyset) = 0$ and $m(C_2) = 1$. Let $0 < x_1 \leq 1$, $0 < y_1 \leq 1$, and $\emptyset$ and C_2 be given by

$$\emptyset = \{f \in C_2; f(x_1, y_1) \in \emptyset_{R_1}\} \quad \text{and} \quad C_2\{f \in C_2; f(x_1, y_1) \in R_1\}$$

then by (2.2), (2.3)

$$\begin{aligned} m(\emptyset) &= \frac{1}{(\pi x_1 y_1)^{1/2}} \int_{\phi_R} \exp \left\{ -\frac{u_{11}^2}{x_1 y_1} \right\} du_{11} = 0, \\ m(C_2) &= \frac{1}{(\pi x_1 y_1)^{1/2}} \int_{R_1} \exp \left\{ -\frac{u_{11}^2}{x_1 y_1} \right\} du_{11} = 1. \end{aligned}$$

We also point out that $m(I)$ is additive i.e. if $I_1, I_2 \in \mathcal{J}$, $I_1 \cap I_2 = \emptyset$ and $I_1 \cup I_2 \in \mathcal{J}$ then $m(I_1 \cup I_2) = m(I_1) + m(I_2)$. This can be easily seen if we extend, if necessary, the restricting sets of the two intervals to two sets in the same Euclidean space by adding restriction points and trivial restrictions on the additional restriction points.

5. Countable additivity of $m(I)$. To show that $m(I)$ is a measure on $\mathcal{J}$ it remains to show that $m(I)$ is countably additive, i.e. if $\{I_n\}$ is a countable collection of elements of $\mathcal{J}$ such that $I_i \cap I_j = \emptyset$ for $i \neq j$ and $\bigcup_{n=1}^{\infty} I_n \in \mathcal{J}$, then $m(\bigcup_{n=1}^{\infty} I_n) = \sum_{n=1}^{\infty} m(I_n)$. In §5 we prove Theorem I which is an estimate of $m(I)$ when I is an interval disjoint from a subset of C_2 defined by a Hölder condition. The proof of countable additivity of $m(I)$ is based on this estimate and is given in Theorem II, §8.

5.1. THEOREM I. *Let γ be a fixed constant satisfying $0 < \gamma < 1/2$ and a be an arbitrary positive number. Let a subset of C_2 , A_a be defined by*

$$(5.1) \quad A_a = \{f \in C_2; |f(x_2, y_2) - f(x_1, y_1)| \leq a[(x_2 - x_1)^2 + (y_2 - y_1)^2]^{\gamma/2}, 0 \leq x_1, y_1, x_2, y_2 \leq 1\}.$$

Then for any interval I disjoint from A_a

$$(5.2) \quad m(I) < ca^{-8/(1-2\gamma)}$$

where c is a positive number and is independent of a .

We prove Theorem I by showing that if an element f of C_2 does not belong to A_a then it belongs to an element of a finite collection of intervals $\{J_n\}$ so that if $I \cap A_a = \emptyset$ then $I \subset \bigcup_n J_n$ and $m(I) \leq \sum_n m(J_n)$. The intervals J_n are so chosen that $\sum_n m(J_n) < ca^{-8/(1-2\gamma)}$. The above is done by means of Lemmas 1-4 which we prove in §§5.2-5.5. The proof of Theorem I itself is given in §5.6.

5.2. The first lemma.

NOTATION. Let n be a positive integer and consider two sequences of numbers $0 = \xi_0 < \xi_1 < \dots < \xi_{2^n} = 1$, $0 = \eta_0 < \eta_1 < \dots < \eta_{2^n} = 1$ where $\xi_j, \eta_j = j/2^n$ for $j = 0, 2, 4, 6, \dots, 2^n$. Let $\mathcal{P}^k$ be the collection of points of the unit square defined by

$$\mathcal{P}^k = \{P^k\{l, m\} = (\xi_{2^k l}, \eta_{2^k m}), l, m = 0, 1, 2, \dots, 2^{n-k}\}, \quad k = 0, 1, 2, \dots, n.$$

We shall often write P^k to mean a member of $\mathcal{P}^k$. Let $X^k\{l, m\}$ be the straight segment connecting the two points $P^k\{l-1, m\}$ and $P^k\{l, m\}$ for $l = 1, 2, \dots, 2^{n-k}, m = 0, 1, 2, \dots, 2^{n-k}, k = 0, 1, 2, \dots, n$ and $Y^k\{l, m\}$ be the straight segment connecting the two points $P^k\{l, m-1\}$ and $P^k\{l, m\}$ for $l = 0, 1, 2, \dots, 2^{n-k}, m = 1, 2, \dots, 2^{n-k}, k = 0, 1, 2, \dots, n$. When we are not particularly concerned about their positions we will write merely X^k and Y^k for $X^k\{l, m\}$ and $Y^k\{l, m\}$.

By $\mathcal{P}^0$ we mean the collection of right triangles with vertices $P^0\{l-1, m-1\}$,

$P^0\{l, m-1\}$, $P^0\{l, m\}$ or with vertices $P^0\{l-1, m-1\}$, $P^0\{l-1, m\}$, $P^0\{l, m\}$, $(l, m=1, 2, \dots, 2^n)$ and by $\mathfrak{Q}^1$ we mean the collection of squares with vertices $P^1\{l-1, m-1\}$, $P^1\{l, m-1\}$, $P^1\{l-1, m\}$, $P^1\{l, m\}$, $(l, m=1, 2, \dots, 2^{n-1})$. The letter Q is reserved for the unit square.

The length of $X^k\{l, m\}$ and $Y^k\{l, m\}$ will be denoted by λ_k . Then $\lambda_k = 2^k/2^n = 2^{k-n}$ independently of l and m in case $k=1, 2, \dots, n$, but when $k=0$, λ_k depends on l and m and we only have the estimate $0 < \lambda_0 < \lambda_1 = 2^{1-n}$. Every element of $\mathfrak{Q}^1$ has four sides of equal length λ_1 .

For any two points $P_1(x_1, y_1)$, $P_2(x_2, y_2) \in Q$, the symbols $d(P_1, P_2)$, $d_x(P_1, P_2)$, $d_y(P_1, P_2)$ mean

$$d(P_1, P_2) = [(x_2 - x_1)^2 + (y_2 - y_1)^2]^{1/2}, \quad d_x(P_1, P_2) = |x_2 - x_1|, \\ d_y(P_1, P_2) = |y_2 - y_1|.$$

In connection with the above definitions we make a few remarks.

REMARK 1. From the definition of $\mathcal{O}^k$ it follows that

$$\mathcal{O}^k \supset \mathcal{O}^{k+1} \quad (k = 0, 1, 2, \dots, n-1).$$

Thus for any point on Q which is also an element of $\mathcal{O}^0$, the superscript k is not unique. However the largest superscript for the point is unique and will be called the index of the point. Then it follows that if k_0 is the index of $P \in \mathcal{O}^0$, then $P \in \mathcal{O}^k$ for $k \leq k_0$ and $P \notin \mathcal{O}^k$ for $k > k_0$. On the other hand for a segment on Q which is an X^k or a Y^k the superscript k is unique and such a segment will be referred to as an edge of index k .

REMARK 2. If $P = P^{k_0}\{l, m\}$ where k_0 is the index of P and $P \in X^k$ then either P is an end point of X^k and hence $P \in \mathcal{O}^k$, $k_0 \geq k$, or P is not an end point of X^k and hence $P \notin \mathcal{O}^k$, $k_0 < k$. In the latter case $P^{k_0}\{l \pm 1, m\} \in \mathcal{O}^{k_0+1}$, where $k_0 + 1 \leq k$. A similar statement holds when $P \in Y^k$.

REMARK 3. Suppose $P_0 = P^{k_0}\{l, m_0\}$ where k_0 is the index of P_0 and P_0 is on some Y^k . If P_0 is not an end point of Y^k , then there is a sequence of points $P_0, P_1, P_2, \dots, P_\beta$ on Y^k with decreasing (or increasing, if you wish) y -coordinates such that the indices $k_0, k_1, k_2, \dots, k_{\beta-1}$ of $P_0, P_1, P_2, \dots, P_{\beta-1}$ satisfy $k_0 < k_1 < k_2 < \dots < k_\beta = k$; in particular, P_β is an endpoint of Y^k and $d(P_0, P_1) = \lambda_{k_0}$, $d(P_1, P_2) = \lambda_{k_1}$, $\dots$, $d(P_{\beta-1}, P_\beta) = \lambda_{k_{\beta-1}}$. A similar statement holds when P_0 is on some X^k .

Proof. If P_0 is not an endpoint of Y^k , i.e. if $P_0 \notin \mathcal{O}^k$ then $k_0 < k$. Let $P_1 = P^{k_0}\{l, m_0-1\}$ which belongs to $\mathcal{O}^{k_0+1}$ by Remark 2. If $P_1 \in \mathcal{O}^k$, let $P_1 = P^{k_1}\{l_1, m_1\}$. If $P_1 \notin \mathcal{O}^k$, let k_1 be the index of P_1 and $P_1 = P^{k_1}\{l_1, m_1\}$ where $k_0 < k_0 + 1 \leq k_1$ and $k_1 < k$. We now repeat the process by letting $P_2 = P^{k_1}\{l_1, m_1-1\}$ which belongs to $\mathcal{O}^{k_1+1}$ by Remark 2. If $P_2 \in \mathcal{O}^k$, let $P_2 = P^{k_2}\{l_2, m_2\}$. If $P_2 \notin \mathcal{O}^k$, let k_2 be the index of P_2 and $P_2 = P^{k_2}\{l_2, m_2\}$ where $k_1 < k_1 + 1 \leq k_2$ and $k_2 < k$. Thus repeating we obtain a strictly increasing sequence of integers $k_0 < k_1 < k_2 < \dots$ each of which satisfies $k_i \leq k$. Since the difference between k and k_0 is finite, k is reached in a finite number of

steps, say in β steps. Then we have $P_\beta \in \mathcal{O}^{k_\beta}$ with $k_\beta = k$. By the choice of $P_1, P_2, \dots, P_\beta$ it is clear that $d(P_0, P_1) = \lambda_{k_0}, d(P_1, P_2) = \lambda_{k_1}, \dots, d(P_{\beta-1}, P_\beta) = \lambda_{k_\beta}$.

We now state and prove Lemma 1 with the Remarks.

LEMMA 1. *Let $f(P)$ be a real valued function defined on $\mathcal{O}^0$. Suppose $f(P)$ is such that if P_1, P_2 are the endpoints of some X^k or Y^k then*

$$(5.3) \quad |f(P_2) - f(P_1)| \leq bad^\gamma(P_1, P_2) \text{ where } a > 0, b = (1 - 2^{-\gamma})/16$$

and

$$0 < \gamma < 1/2.$$

Then for any $P_1, P_2 \in \mathcal{O}^0$,

$$(5.4) \quad |f(P_2) - f(P_1)| \leq ad^\gamma(P_1, P_2).$$

Proof. Let $P_1, P_2 \in \mathcal{O}^0$ and $P_1 = (\xi_p, \eta_{p'})$, $P_2 = (\xi_q, \eta_{q'})$ and $P_3 = (\xi_q, \eta_{p'})$. Since d^γ does not satisfy the triangle law, one cannot get a satisfactory estimate by going by short steps in a straight line from P_1 to P_3 . In order to take fewer (and hence longer) steps, it is necessary to zigzag along the edges of larger and larger squares for which the inequality is known to hold. In this way the number of steps of each length is kept bounded, and the sum of d^γ distances can be satisfactorily estimated.

Consider $f(P_3) - f(P_1)$. If $p = q$, then $P_1 = P_3$ and the difference is 0. Therefore assume, without loss of generality in the proof, that $p < q$, and consider the set of integers $p, p+1, \dots, q$. Everyone of these integers except possibly for p which may be 0, can be written as $l2^k$ with an odd integer l . For an odd integer the exponent k is 0 and for an even integer k can not be 0 and is the largest possible integer for that number because l is an odd integer. Let k be the greatest of all the unique exponents of $p, p+1, \dots, q$. Let r be a member of the set $\{p, p+1, \dots, q\}$ with this greatest exponent k . Then r is unique for the existence of two such numbers would contradict the maximality of k . Now let $r = l2^k$. We have $p \leq r \leq q$ with $p < q$. Let $P_3^* = (\xi_r, \eta_{p'})$ and consider $f(P_3) - f(P_3^*)$. If $r = q$ then $P_3 = P_3^*$ and the difference is 0. Let us assume then that $r < q$ and express $q - r$ in the binary scale

$$(5.5) \quad q - r = 2^{k_\alpha} + 2^{k_{\alpha-1}} + \dots + 2^{k_1} + 2^{k_0}$$

with $k_\alpha > k_{\alpha-1} > \dots > k_1 > k_0 \geq 0$.

We point out that $k > k_\alpha$, for otherwise the choice of r would be contradicted.

It is clear that $P_3^* = (\xi_r, \eta_{p'})$ is on some Y^k and $P_3 = (\xi_q, \eta_{p'})$ is on some Y^{k_0} . If P_3 is not an endpoint of the Y^{k_0} then according to Remark 3 there exists a sequence of points $P_{00} (= P_3), P_{01}, P_{02}, \dots, P_{0, \beta_0}$ on the Y^{k_0} with decreasing y coordinates such that the indices $k_{00}, k_{01}, k_{02}, \dots, k_{0, \beta_0-1}$ of $P_{00}, P_{01}, P_{02}, \dots, P_{0, \beta_0-1}$ satisfy $k_{00} < k_{01} < k_{02} < \dots < k_{0, \beta_0} = k_0$ and furthermore

$d(P_{00}, P_{01}) = \lambda_{k_{00}}$, $d(P_{01}, P_{02}) = \lambda_{k_{01}}$, $\dots$, $d(P_{0, \beta_0-1}, P_{0, \beta_0}) = \lambda_{k_{0, \beta_0-1}}$, and in particular P_{0, β_0} is an endpoint of the Y^{k_0} . Let $P_3 = P_{0, \beta_0} = P^{k_0}\{l_0, m_0\}$. If P_3 is an endpoint of the Y^{k_0} to begin with, let $P_3 = P_{0, \beta_0} = P^{k_0}\{l_0, m_0\}$ with $\beta_0 = 0$. In any case $P^{k_0}\{l_0-1, m_0\}$ is on some Y^{k_1} by (5.5). Now we iterate the above process. If $P^{k_0}\{l_0-1, m_0\}$ is not an endpoint of the Y^{k_1} , then according to Remark 3, there exists a sequence of points $P_{10}(=P^{k_0}\{l_0-1, m_0\})$, P_{11} , P_{12} , $\dots$, P_{1, β_1} on the Y^{k_1} with decreasing y coordinates such that the indices k_{10} , k_{11} , k_{12} , $\dots$, k_{1, β_1-1} of P_{10} , P_{11} , P_{12} , $\dots$, P_{1, β_1-1} satisfy $k_0 \leq k_{10} < k_{11} < k_{12} < \dots < k_{1, \beta_1} = k_1$, $d(P_{10}, P_{11}) = \lambda_{k_{10}}$, $d(P_{11}, P_{12}) = \lambda_{k_{11}}$, $\dots$, $d(P_{1, \beta_1-1}, P_{1, \beta_1}) = \lambda_{k_{1, \beta_1-1}}$ and in particular P_{1, β_1} is an endpoint of the Y^{k_1} . Let $P_{1, \beta_1} = P^{k_1}\{l_1, m_1\}$. If $P^{k_0}\{l_0-1, m_0\}$ is an endpoint of Y^{k_1} to begin with, let $P^{k_0}(l_0-1, m_0) = P_{1, \beta_1} = P^{k_1}(l_1, m_1)$ with $\beta_1 = 0$. In any case $P^{k_1}(l_1-1, m_1)$ is on some Y^{k_2} by (5.5). Thus repeating we reach a point $P_{\alpha, \beta_\alpha} = P^{k_\alpha}\{l_\alpha, m_\alpha\}$ which is an endpoint of some Y^{k_α} . Then by (5.5), $P^{k_\alpha}\{l_\alpha-1, m_\alpha\}$ is on some Y^k and has the same x coordinate as P_3^* . Let $P^{k_\alpha}\{l_\alpha-1, m_\alpha\} = P_{\alpha+1, 0} = P^{k_{\alpha+1}}\{l_{\alpha+1}, m_{\alpha+1}\}$ with $k_{\alpha, \beta_\alpha} \leq k_{\alpha+1} \leq k$. In this manner we construct a sequence of points which consists of $\alpha+2$ subsequences, $\{P_{00}, P_{01}, P_{02}, \dots, P_{0, \beta_0}\}$, $\{P_{10}, P_{11}, P_{12}, \dots, P_{1, \beta_1}\}$, $\dots$, $\{P_{\alpha, 0}, P_{\alpha, 1}, P_{\alpha, 2}, \dots, P_{\alpha, \beta_\alpha}\}$, $\{P_{\alpha+1, 0}\}$ with $\beta_0, \beta_1, \dots, \beta_\alpha \geq 0$ and a sequence of integers which consists of $\alpha+2$ subsequences

$$\{k_{00}, k_{01}, k_{02}, \dots, k_{0, \beta_0}\}, \{k_{10}, k_{11}, k_{12}, \dots, k_{1, \beta_1}\}, \dots, \\ \cdot \{k_{\alpha, 0}, k_{\alpha, 1}, k_{\alpha, 2}, \dots, k_{\alpha, \beta_\alpha}\}, \{k_{\alpha+1}\}$$

with the property $k_{00} < k_{11} < k_{12} < \dots < k_{0, \beta_0} \leq k_{10} < k_{11} < k_{12} < \dots < k_{1, \beta_1} \leq k_{20} < \dots < k_{\alpha-1, \beta_{\alpha-1}} \leq k_{\alpha, 0} < k_{\alpha, 1} < k_{\alpha, 2} < \dots < k_{\alpha, \beta_\alpha} \leq k_{\alpha+1}$. Furthermore P_{0, β_0} , P_{1, β_1} , $\dots$, P_{α, β_α} , $P_{\alpha+1, 0}$ have $k_{0, \beta_0} = k_0$, $k_{1, \beta_1} = k_1$, $\dots$, $k_{\alpha, \beta_\alpha} = k_\alpha$, $k_{\alpha+1}$ as their superscripts and each $P_{i, j}$ of the rest of the sequence has $k_{i, j}$ as its index. Any two successive points in the sequence are the endpoints of an edge whose index is equal to the suffix of the first of the two points. This edge is parallel to the y -axis in case the two points belong to one of the $\alpha+2$ subsequences and it is parallel to the x -axis if they belong to two consecutive subsequences. In particular $P_{00} = P_3$ and $P_{\alpha+1, 0}$ has the same x -coordinate as P_3^* .

Let the projection on the Y^k containing P_3^* of each member $P_{i, j}$ of the sequence $P_{00}, P_{01}, \dots, P_{\alpha+1, 0}$ be denoted by $P_{i, j}^*$ and consider the sequence $P_{00}^*, P_{10}^*, \dots, P_{\alpha+1, 0}^*$. Any two successive points are the endpoints of an edge parallel to the y -axis with an index which is equal to the suffix of the first of the two points provided the preimages of these two points belong to one of the $\alpha+2$ subsequences, otherwise they are coincident. We notice that in particular $P_{\alpha+1, 0}^* = P_{\alpha+1, 0}$. Let us use the sequence of points $P_{00}(=P_3)$, $P_{0, 1}$, $\dots$, P_{α, β_α} , $P_{\alpha+1, 0}(=P_{\alpha+1, 0}^* = P_{\alpha, \beta_\alpha}^*)$, $P_{\alpha, \beta_\alpha-1}^*$, $\dots$, P_{01}^* , $P_{00}^*(=P_3^*)$ as intermediate points between P_3 and P_3^* in estimating $f(P_3) - f(P_3^*)$. Then by (5.3)

$$|f(P_3) - f(P_3^*)| \leq 2ba \sum_{i=0}^{k_\alpha} \lambda_i^\gamma < 2ba \left(2^{(1-n)\gamma} + \sum_{i=1}^{k_\alpha} 2^{(i-n)\gamma} \right).$$

From the fact that $0 < \gamma < 1/2$, it follows that $2^\gamma < 1/(1 - 2^{-\gamma})$, $2^{(1-n)\gamma} < 2^{-n\gamma}/(1 - 2^{-\gamma}) = \sum_{i=0}^{-\infty} 2^{(i-n)\gamma}$ and hence

$$\begin{aligned}
 |f(P_3) - f(P_3^*)| &\leq 2ba \sum_{i=k_\alpha}^{-\infty} 2^{(i-n)\gamma} \\
 (5.6) \qquad &= 2ba 2^{(k_\alpha-n)\gamma} \sum_{i=k_\alpha}^{-\infty} 2^{(i-k_\alpha)\gamma} = \frac{2ba}{1 - 2^{-\gamma}} 2^{(k_\alpha-n)\gamma}.
 \end{aligned}$$

Let us then estimate $d(P_3, P_3^*)$. The x -coordinates of P_3 and P_3^* are ξ_q and ξ_r and $q - r$ is given by (5.5). If $k_\alpha = 0$ or 1 , in (5.5), then $q - r \leq 3$ and by (5.3)

$$\begin{aligned}
 |f(P_3) - f(P_3^*)| &< 3bad^\gamma(P_3, P_3^*) < \frac{3ba}{1 - 2^{-\gamma}} d^\gamma(P_3, P_3^*) \\
 (5.7) \qquad &\qquad\qquad\qquad \text{for } k_\alpha = 0, 1.
 \end{aligned}$$

Let $k_\alpha \geq 2$. Since $\xi_q > (q-1)/2^n$ whether q is even or odd and similarly $\xi_r < (r+1)/2^n$ we have, according to (5.5)

$$\begin{aligned}
 d(P_3, P_3^*) = \xi_q - \xi_r &\geq \frac{(q-1) - (r+1)}{2^n} \geq \frac{2^{k_\alpha} - 2}{2^n} \geq \frac{1}{2} 2^{k_\alpha-n}, \\
 (5.8) \qquad d^\gamma(P_3, P_3^*) &\geq \frac{1}{2} 2^{(k_\alpha-n)\gamma}.
 \end{aligned}$$

From (5.6), (5.8)

$$(5.9) \qquad |f(P_3) - f(P_3^*)| < \frac{4ba}{1 - 2^{-\gamma}} d^\gamma(P_3, P_3^*) \quad \text{for } k_\alpha \geq 2.$$

By (5.7), (5.9)

$$(5.10) \qquad |f(P_3) - f(P_3^*)| < \frac{4ba}{1 - 2^{-\gamma}} d^\gamma(P_3, P_3^*).$$

Exactly the same estimate as (5.10) holds for the pair P_1 and P_3^* and from the fact $d(P_1, P_3) \geq d(P_3, P_3^*)$, $d(P_1, P_3^*)$, we have

$$(5.11) \qquad |f(P_3) - f(P_1)| < \frac{8ba}{1 - 2^{-\gamma}} d^\gamma(P_1, P_3).$$

Again exactly the same estimate as (5.11) holds for the pair P_2 and P_3 and from the fact that $d(P_1, P_2) \geq d(P_1, P_3)$, $d(P_2, P_3)$ and

$$|f(P_2) - f(P_1)| < \frac{16ba}{1 - 2^{-\gamma}} d^\gamma(P_1, P_2) = ad^\gamma(P_1, P_2).$$

This completes the proof of Lemma 1.

5.3. LEMMA 2. Let a real number be assigned to each element of $\mathcal{O}^0$. Let $f(P)$ be defined on the unit square Q in such a way that $f(P)$ takes on the preassigned values on $\mathcal{O}^0$, is linear on each element of the collection of triangles $\mathcal{O}^0$ and for any $P_1, P_2 \in \mathcal{O}^0$

$$(5.12) \quad |f(P_2) - f(P_1)| \leq ad^\gamma(P_1, P_2).$$

Then for any $P_1, P_2 \in Q$,

$$(5.13) \quad |f(P_2) - f(P_1)| \leq 22ad^\gamma(P_1, P_2).$$

Proof. Let $P_1, P_2 \in Q$ be arbitrarily given. Let P_3 have the same x -coordinate as P_2 and the same y -coordinate as P_1 . Consider $f(P_3) - f(P_1)$.

CASE 1. If P_1, P_3 are contained in one element of $\mathcal{O}^0$ let P_1^*, P_3^* be the projections of P_1, P_3 on the side $P_4 P_5$ of the triangle which is parallel to the x -axis. Then from the linearity of $f(P)$ on the triangle and by (5.12)

$$(5.14) \quad \begin{aligned} |f(P_3) - f(P_1)| &= |f(P_3^*) - f(P_1^*)| = \frac{d(P_1, P_3)}{d(P_4, P_5)} |f(P_3^*) - f(P_4^*)| \\ &\leq \frac{d^\gamma(P_1, P_3)}{d^\gamma(P_4, P_5)} |f(P_3^*) - f(P_4^*)| \leq ad^\gamma(P_1, P_3). \end{aligned}$$

CASE 2. If P_1, P_3 are contained in one element of $\mathcal{Q}^1$, then the segment $P_1 P_3$ is contained in at most four elements of $\mathcal{O}^0$. Using the intersections of $P_1 P_3$ with the boundaries of these triangles as intermediate points between P_1 and P_3 we have by (5.14)

$$(5.15) \quad |f(P_3) - f(P_1)| \leq 4ad^\gamma(P_1, P_3).$$

CASE 3. If P_1, P_3 are contained in two adjacent elements of $\mathcal{Q}^1$ then the segment $P_1 P_3$ is contained in at most eight elements of $\mathcal{O}^0$ and hence

$$(5.16) \quad |f(P_3) - f(P_1)| \leq 8ad^\gamma(P_1, P_3).$$

CASE 4. Finally when P_1, P_3 are not in one or two adjacent elements of $\mathcal{Q}^1$, let Q_1^1, Q_3^1 be the two elements of $\mathcal{Q}^1$ which contain P_1, P_3 respectively. Let the intersections of the segment $P_1 P_3$ with the boundaries of Q_1^1, Q_3^1 be P_{11}, P_{31} respectively. Of the two endpoints of the edge of Q_1^1 that contains P_{11} , let P_{12} be the one contained in the same element of $\mathcal{O}^0$ as P_{11} and let P_{32} be chosen in the same way. Then P_1, P_{32} have the same y -coordinates. Consider the chain of points $P_1, P_{11}, P_{12}, P_{32}, P_{31}, P_3$. For the pair P_1, P_{11} and the pair P_{31}, P_3 , the estimate (5.15) holds; for the pair P_{11}, P_{12} and the pair P_{32}, P_{31} , the estimate (5.14) holds and for the pair P_{12}, P_{32} the assumption (5.12) holds. Furthermore $d(P_1, P_3) \geq d(P_{12}, P_{32})$ and $d(P_{12}, P_{32})$ is greater than any one of $d(P_1, P_{11}), d(P_{11}, P_{12}), d(P_{32}, P_{31}), d(P_{31}, P_3)$. Hence

$$(5.17) \quad |f(P_3) - f(P_1)| < 11ad^\gamma(P_1, P_3).$$

From (5.14), (5.15), (5.16), (5.17), the estimate (5.17) for P_1, P_3 for all cases holds and with exactly the same estimate for the pair P_1, P_2 we conclude that

$$|f(P_2) - f(P_1)| < 22ad^\gamma(P_1, P_2).$$

Combining Lemma 1 and Lemma 2 we have:

5.4. LEMMA 3. *Let $f(P)$ be a real valued function defined and continuous on the unit square Q and linear on each element of $\mathfrak{D}^0$. Furthermore let $f(P)$ be such that if P_1, P_2 are the end points of some X^k or Y^k*

$$(5.18) \quad |f(P_2) - f(P_1)| \leq \frac{1}{22 \times 16} (1 - 2^{-\gamma})ad^\gamma(P_1, P_2)$$

holds. Then for any $P_1, P_2 \in Q$

$$(5.19) \quad |f(P_2) - f(P_1)| \leq ad^\gamma(P_1, P_2).$$

5.5. LEMMA 4. *Let $0 \leq x_1 < x_2 \leq 1, 0 \leq y_1 < y_2 \leq 1$. Then for the interval*

$$(5.20) \quad I = \{f \in C_2; |f(x_2, y_1) - f(x_1, y_1)| > a|x_2 - x_1|^\gamma\},$$

$m(I) = 0$ in case $y_1 = 0$ and if $y_1 \neq 0$

$$(5.21) \quad m(I) \leq \exp \left\{ -\frac{a^2}{(x_2 - x_1)^{1-2\gamma}y_1} \right\}.$$

Similar estimates hold for the interval

$$I = \{f \in C_2; |f(x_1, y_2) - f(x_1, y_1)| > a|y_2 - y_1|^\gamma\}.$$

Proof. The set I given by (5.20) is an interval with restriction points $(x_1, y_1), (x_2, y_1)$ and restricting set $E = \{(u_{11}, u_{21}) \in R_2; |u_{21} - u_{11}| > a|x_2 - x_1|^\gamma\}$, a Lebesgue measurable set in R_2 . In case $y_1 = 0$, then since $f(x, 0) = 0$ for $0 \leq x \leq 1$, the interval defined by (5.20) is an empty set and $m(I) = 0$.

Let $y_1 \neq 0$. By (2.2), (2.3)

$$m(I) = \frac{1}{\pi[x_1(x_2 - x_1)]^{1/2}y_1} \iint_E \exp \left\{ -\frac{u_{11}^2}{x_1y_1} - \frac{(u_{21} - u_{11})^2}{(x_2 - x_1)y_1} \right\} du_{11} du_{12}.$$

With the transformation $v_1 = u_{11}, v_2 = u_{21} - u_{11}$, the restricting set E becomes $E = \{(v_1, v_2) \in R_2, -\infty < v_1 < \infty, |v_2| > b\}$ where $b = a|x_2 - x_1|^\gamma$. Thus

$$m(I) = \frac{1}{\pi[x_1(x_2 - x_1)]^{1/2}y_1} \left\{ \int_{-\infty}^{\infty} \exp \left\{ -\frac{v_1^2}{x_1y_1} \right\} dv_1 \right\} \\ \cdot \left\{ \int_{|v_2| > b} \exp \left\{ -\frac{v_2^2}{(x_2 - x_1)y_1} \right\} dv_2 \right\}.$$

The value of the first integral is $(\pi x_1 y_1)^{1/2}$. To estimate the second integral let $w = v_2 - b$; then

$$\begin{aligned} \int_{|v_2| > b} \exp \left\{ \frac{-v_2^2}{(x_2 - x_1)y_1} \right\} dv_2 &= 2 \int_0^\infty \exp \left\{ \frac{-(w+b)^2}{(x_2 - x_1)y_1} \right\} dw \\ &\leq 2 \exp \left\{ \frac{-b^2}{(x_2 - x_1)y_1} \right\} \int_0^\infty \exp \left\{ \frac{-w^2}{(x_2 - x_1)y_1} \right\} dw. \end{aligned}$$

The value of the last integral is $(\pi(x_2 - x_1)y_1)^{1/2}/2$. From these evaluations and estimates, (5.21) follows.

5.5. Proof of Theorem I. With notations introduced in §5.2, the set A_a may be written: $A_a = \{f \in C_2; |f(P_2) - f(P_1)| \leq \text{ad}^\gamma(P_1, P_2), P_1, P_2 \in Q\}$. Let $I \in \mathcal{J}$, $I \cap A_a = \emptyset$ and $I = \{f \in C_2, [f(x_1, y_1), \dots, f(x_s, y_t)] \in E\}$ where $0 < x_1 < x_2 < \dots < x_s \leq 1$, $0 < y_1 < y_2 < \dots < y_t \leq 1$ and E is a Lebesgue measurable set in R_{st} . Let n be so large that

$$2^{1-n} < \min\{x_1, x_2 - x_1, \dots, x_s - x_{s-1}, y_1, y_2 - y_1, \dots, y_t - y_{t-1}\}$$

and $2^{1-n} < 1 - x_s, 1 - y_t$ in case $x_s \neq 1, y_t \neq 1$. Consider partitions of the intervals $0 \leq x \leq 1, 0 \leq y \leq 1$ into the subintervals of length 2^{1-n} by the partition points $\xi_{2l} = 2l/2^n$ ($l = 0, 1, 2, \dots, 2^{n-1}$), $\eta_{2m} = 2m/2^n$ ($m = 0, 1, 2, \dots, 2^{n-1}$). Each interval $\xi_{2(l-1)} < x < \xi_{2l}$ contains at most one x_i , ($i = 1, 2, \dots, s$). If it contains one x_i let $\xi_{2l-1} = x_i$; otherwise let $\xi_{2l-1} = (\xi_{2(l-1)} + \xi_{2l})/2$. Then $\{x_1, x_2, \dots, x_s\} \subset \{\xi_1, \xi_2, \dots, \xi_{2^n}\}$. We choose odd numbered η_j in the same fashion so that $\{y_1, y_2, \dots, y_t\} \subset \{\eta_1, \eta_2, \dots, \eta_{2^n}\}$. Let

$$\mathcal{O}^0 = \{(\xi_1, \eta_1), \dots, (\xi_{2^n}, \eta_{2^n})\} \supset \{(x_1, y_1), \dots, (x_s, y_t)\}.$$

Let $\mathcal{O}^0$ be restriction points of I by adding trivial restrictions at the additional restriction points and extending E to a Lebesgue measurable set E' in R_4^n .

For any $f \in I$, let f^* be such that $f^* = f$ on $\mathcal{O}^0$ and f^* is linear on each element of $\mathcal{O}^0$. Since f^* agrees with f on the collection of restriction points $\mathcal{O}^0$ of I , $f^* \in I$ and hence $f^* \notin A_a$. Then by Lemma 3 f^* must violate (5.18) at the endpoints of some X^k or Y^k . Since f agrees with f^* on $\mathcal{O}^0$ which contains endpoints of X^k, Y^k f violates (5.18) at the endpoints of some X^k or Y^k . In other words $f \in J_x\{k, l, m\}$ or $f \in J_y\{k, l, m\}$ for some $k = 0, 1, 2, \dots, n; l, m = 1, 2, \dots, 2^{n-k}$ where

$$\begin{aligned} J_x\{k, l, m\} &= \{f \in C_2; |f(P^k\{l, m\}) - f(P^k\{l-1, m\})| \\ &> bd^\gamma(P^k\{l-1, m\}, P^k\{l, m\}), \\ J_y\{k, l, m\} &= \{f \in C_2; |f(P^k\{l, m\}) - f(P^k\{l, m-1\})| \\ &> bd^\gamma(P^k\{l, m-1\}, P^k\{l, m\}), \end{aligned}$$

$$(5.22) \quad b = \frac{1}{22 \times 16} (1 - 2^{-\gamma})a.$$

We remember that $J_x\{k, l, 0\} = J_y\{k, 0, m\} = \emptyset$.

It follows then that

$$I \subset \bigcup_{k=0}^n \bigcup_{l=1}^{2^{n-k}} \bigcup_{m=1}^{2^{n-k}} (J_x\{k, l, m\} \cup J_y\{k, l, m\}),$$

and from the finite additivity of m

$$m(I) \leq \sum_{k=0}^n \sum_{l=1}^{2^{n-k}} \sum_{m=1}^{2^{n-k}} \{m(J_x\{k, l, m\}) + m(J_y\{k, l, m\})\}.$$

By Lemma 4

$$m(J_x\{k, l, m\}) \leq \exp \left\{ \frac{-b^2}{(\xi_{l2^k} - \xi_{(l-1)2^k})^{1-2\gamma} \eta_{m,2^k}} \right\} \leq \exp \left\{ \frac{-b^2}{(\xi_{l2^k} - \xi_{(l-1)2^k})^{1-2\gamma}} \right\},$$

and from the independence of the last estimate from m and from the independence and the similar estimate for $m(J_y\{k, l, m\})$ from l

$$m(I) \leq 2 \sum_{k=0}^n \sum_{l=1}^{2^{n-k}} 2^{n-k} \exp \left\{ \frac{-b^2}{(\xi_{l2^k} - \xi_{(l-1)2^k})^{1-2\gamma}} \right\}.$$

In the summation above, for $k=0$, $\xi_l - \xi_{l-1} < 2/2^n$ and for $k \geq 1$, $\xi_{l2^k} - \xi_{(l-1)2^k} = 2^{k-n}$ and consequently

$$m(I) \leq 2 \left[4^n \exp \{ -b^2 2^{(n-1)(1-2\gamma)} \} + \sum_{k=1}^n 4^{n-k} \exp \{ -b^2 2^{(n-k)(1-2\gamma)} \} \right].$$

Reversing the order of summation in the second term above and then noticing that the first term above is four times the $(n-1)$ st member of the second term after the reversion, we have

$$\begin{aligned} m(I) &\leq 2 \left[4 \times 4^{n-1} \exp \{ -b^2 2^{(n-1)(1-2\gamma)} \} + \sum_{k=1}^n 4^{k-1} \exp \{ -b^2 2^{(k-1)(1-2\gamma)} \} \right] \\ (5.23) \quad &< 10 \sum_{k=1}^{\infty} 4^{k-1} \exp \{ -b^2 2^{(k-1)(1-2\gamma)} \} \\ &= 10 \sum_{k=0}^{\infty} 4^{-k} 4^{2k} \exp \{ -b^2 2^{2k(1-2\gamma)/2} \}. \end{aligned}$$

To estimate the last series let us consider the function $\phi(u) = u^2 \exp \{ -b^2 u^\lambda \}$ for $u \geq 0$ with $\lambda > 0$. This function has exactly one maximum at $u_{\max} = (2/\lambda b^2)^{1/\lambda}$ and the maximum value is given by $\phi(u_{\max}) = (\lambda b^2 e/2)^{-2/\lambda}$. If we identify u with 2^{2k} and λ with $(1-2\gamma)/2$ in the last member of (5.23) then

$$4^{2k} \exp \left\{ -b^2 2^{2k(1-2\gamma)/2} \right\} \leq \left\{ \frac{(1-2\gamma)b^2 e}{4} \right\}^{-4/(1-2\gamma)},$$

and hence from (5.23), (5.22),

$$\begin{aligned} m(I) &\leq 10 \left\{ \frac{(1-2\gamma)b^2 e}{4} \right\}^{-4/(1-2\gamma)} \sum_{k=0}^{\infty} 4^{-k} \\ &= \frac{40}{3} \left\{ \frac{(1-2\gamma)(1-2\gamma)^2 e}{(2 \times 16 \times 22)^2} \right\}^{-4/(1-2\gamma)} a^{-8/(1-2\gamma)}. \end{aligned}$$

This completes the proof of Theorem I.

6. Compactness of A_a .

LEMMA 5. *The subset A_a of C_2 defined by*

$$A_a = \{f \in C_2: |f(P_2) - f(P_1)| \leq ad^\gamma(P_1, P_2), P_1, P_2 \in Q\}$$

is compact in itself in the weak topology of C_2 , i.e. for any sequence $\{f_n\} \subset A_a$ there exists a subsequence $\{f_{n_k}\}$ which converges point-wise on Q to an element $f_0 \in A_a$.

Proof. Let $0 = (0, 0)$. Then for any $f \in A_a$, $P \in Q$,

$$(6.1) \quad |f(P)| = |f(P) - f(0)| \leq ad^\gamma(P, 0) \leq 2^{1/2}a.$$

Let $\{f_n\}$ be an arbitrary sequence of elements of A_a and $\{P_\alpha\}$ be a countable collection of points which is dense in Q in the usual topology. For each P_α , the sequence of numbers $\{f_n(P_\alpha)\}$ is bounded according to (6.1) and hence has a convergent subsequence. Let $\{f_{1,n}\}$ be a subsequence of $\{f_n\}$ which converges at P_1 , $\{f_{2,n}\}$ be a subsequence of $\{f_{1,n}\}$ which converges at P_2 and so forth. Then the subsequence $\{g_n\}$ of $\{f_n\}$ where $g_n = f_{n,n}$ converges on $\{P_\alpha\}$. Let us define a function f_0 on $\{P_\alpha\}$ by $f_0(P_\alpha) = \lim_{n \rightarrow \infty} g_n(P_\alpha)$. For any $P_{\alpha_1}, P_{\alpha_2} \in \{P_\alpha\}$, since $g_n \in A_a$,

$$(6.2) \quad |f_0(P_{\alpha_2}) - f_0(P_{\alpha_1})| = \lim_{n \rightarrow \infty} |g_n(P_{\alpha_2}) - g_n(P_{\alpha_1})| \leq ad^\gamma(P_{\alpha_1}, P_{\alpha_2}).$$

To extend the definition of f_0 to the entire Q , let $P \in Q$ and $\{P_i\} \subset \{P_\alpha\}$ be an arbitrary sequence which converges to P and define $f_0(P) = \lim_{i \rightarrow \infty} f_0(P_i)$. The limit exists by Cauchy criterion for $|f_0(P_{i_2}) - f_0(P_{i_1})| \leq ad^\gamma(P_{i_1}, P_{i_2})$ by (6.2) and $\lim_{i_1, i_2 \rightarrow \infty} d^\gamma(P_{i_1}, P_{i_2}) = 0$. The definition of $f_0(P)$ above is unique. For if another sequence $\{P_j\} \subset \{P_\alpha\}$ also converges to P , then

$$\left| \lim_{j \rightarrow \infty} f_0(P_j) - \lim_{i \rightarrow \infty} f_0(P_i) \right| \leq \lim_{i, j \rightarrow \infty} ad^\gamma(P_i, P_j) = 0.$$

The function $f_0(P)$ defined above is continuous on Q . To show this let $\{P_l\} \subset Q$ be an arbitrary sequence which converges to P , and for each P_l let

$\{P_{l,k}\} \subset \{P_\alpha\}$ be a sequence which converges to P_l , and let $\{P_i\} \subset \{P_\alpha\}$ be a sequence which converges to P . Then

$$\begin{aligned} \left| \lim_{l \rightarrow \infty} f_0(P_l) - f_0(P) \right| &= \left| \lim_{l \rightarrow \infty} \lim_{k \rightarrow \infty} \lim_{n \rightarrow \infty} g_n(P_{l,k}) - \lim_{i \rightarrow \infty} \lim_{n \rightarrow \infty} g_n(P_i) \right| \\ &\leq \lim_{l,k,i \rightarrow \infty} ad^\gamma(P_{l,k}, P_i) = 0. \end{aligned}$$

To show that $f_0 \in A_\alpha$ let $P, P' \in Q$ and $\{P_i\}, \{P_j\} \subset \{P_\alpha\}$ be two subsequences which converges to P, P' respectively. Then

$$\begin{aligned} |f_0(P') - f_0(P)| &= \left| \lim_{j \rightarrow \infty} \lim_{n \rightarrow \infty} g_n(P_j) - \lim_{i \rightarrow \infty} \lim_{n \rightarrow \infty} g_n(P_i) \right| \\ &\leq \lim_{i,j \rightarrow \infty} ad^\gamma(P_i, P_j) = ad^\gamma(P, P'). \end{aligned}$$

Finally to show that $\lim_{n \rightarrow \infty} g_n(P) = f_0(P)$ on Q , let $\epsilon > 0$ be given, $\{P_i\} \subset \{P_\alpha\}$ be a sequence which converges to P , i_0 be so large that $d(P_{i_0}, P) \leq (\epsilon/3a)^{1/\gamma}$ and N be such that $|g_n(P_{i_0}) - f_0(P_{i_0})| < \epsilon/3$ for $n \geq N$. Then since $g_n, f_0 \in A_a$

$$\begin{aligned} |g_n(P) - f_0(P)| &\leq |g_n(P) - g_n(P_{i_0})| + |g_n(P_{i_0}) - f_0(P_{i_0})| \\ &\quad + |f_0(P_{i_0}) - f_0(P)| \\ &\leq ad^\gamma(P_{i_0}, P) + \frac{\epsilon}{3} + ad^\gamma(P_{i_0}, P) \leq \epsilon \quad \text{for } n \geq N \end{aligned}$$

and $\lim_{n \rightarrow \infty} g_n(P) = f_0(P)$. This completes the proof that the subsequence $\{g_n\} \subset \{f_n\}$ converges to $f_0 \in A_a$.

COROLLARY. Let $J \in \mathcal{G}$ be defined by st restriction points $(x_1, y_1), \dots, (x_s, y_t)$ and a set G closed in the usual topology of R_{st} . Then $J \cap A_a$ is compact in itself.

Proof. Since a set closed in the usual topology of a Euclidean space is a Lebesgue measurable set, J is indeed an interval. Let a sequence $\{f_n\} \subset J \cap A_a$ be given. By Lemma 5, there exists a subsequence $\{g_n\}$ of $\{f_n\}$ which converges to an element f_0 of A_a . To prove the corollary it remains to show that $f_0 \in J$ also. From the pointwise convergence of $\{g_n\}$ to f_0 on Q and in particular on the restriction points, it follows that

$$\lim_{n \rightarrow \infty} [g_n(x_1, y_1), \dots, g_n(x_s, y_t)] = [f_0(x_1, y_1), \dots, f_0(x_s, y_t)]$$

in the usual topology of R_{st} . Then since $\{f_n\} \subset J$, $[g_n(x_1, y_1), \dots, g_n(x_s, y_t)] \in G$ and since G is closed, $[f_0(x_1, y_1), \dots, f_0(x_s, y_t)] \in G$ and $f_0 \in J$.

7. LEMMA 6. Let $I \in \mathcal{G}$ be defined by st restriction points $(x_1, y_1), \dots, (x_s, y_t)$ and a Lebesgue measurable subset E of R_{st} as restricting set. Then for any $\epsilon > 0$

there exists a closed set $G \subset E$ such that the interval J defined by the same st restriction points and with G as restricting set satisfies $m(I - J) < \epsilon$.

Proof. If E is a Lebesgue measurable set in R_{st} , then for any $\epsilon_0 > 0$ there exists a closed set $G \subset E$ such that $(\text{Leb})m(E - G) < \epsilon_0$. Let

$$\epsilon_0 = \epsilon \{ \pi^{st} [x_1(x_2 - x_1), \dots, (x_s - x_{s-1})]^t [y_1(y_2 - y_1) \dots (y_t - y_{t-1})^s] \}^{1/2}.$$

The interval $I - J$ is defined by the same st restriction points and with the measurable set $E - G$ as restriction set and hence by (2.2), (2.3)

$$\begin{aligned} m(J - I) &= \int_{E-G}^{(st)} \int W\{x_1, \dots, x_s, y_1, \dots, y_t\} du_{11} \dots du_{st} \\ &\leq (\text{Leb})m(E - G) \sup_{E-G} W\{x_1, \dots, x_s, y_1, \dots, y_t\} \leq \epsilon. \end{aligned}$$

8. Countable additivity of $m(I)$.

THEOREM II. The set function $m(I)$ is countably additive on $\mathcal{J}$, i.e., if a sequence of intervals $\{I_n\} \subset \mathcal{J}$ is such that $I_i \cap I_j = \emptyset$ for $i \neq j$ and $I = \bigcup_{n=1}^{\infty} I_n \in \mathcal{J}$, then $m(I) = \sum_{n=1}^{\infty} m(I_n)$.

Proof. (1) Since $\mathcal{J}$ is a field $J_n = (I - \bigcup_{j=1}^n I_j) \in \mathcal{J}$. It can be seen readily that $\bigcap_{n=1}^{\infty} J_n = \emptyset$. Then since $\{J_n\}$ is a monotonically decreasing sequence, $\lim_{n \rightarrow \infty} J_n = \bigcap_{n=1}^{\infty} J_n = \emptyset$. From the fact that $(\bigcup_{j=1}^n I_j) \cap J_n = \emptyset$, $I = (\bigcup_{j=1}^n I_j) \cup J_n$ and m is finite additive,

$$(8.1) \quad m(I) = m\left(\bigcup_{j=1}^n I_j\right) + m(J_n) = \sum_{j=1}^n m(I_j) + m(J_n) \quad \text{for all } n.$$

For the proof of the countable additivity of m we only have to show that $\lim_{n \rightarrow \infty} m(J_n) = 0$, i.e. for given $\epsilon > 0$, there exists an integer n_0 such that $m(J_n) < \epsilon$ for $n \geq n_0$.

(2) Let J_n be defined by $s_n t_n$ restriction points $(x_1^n, y_1^n), \dots, (x_{s_n}^n, y_{t_n}^n)$ with a restricting set E_n which is a Lebesgue measurable subset of $R_{s_n t_n}$. By Lemma 6, there exists a closed set $G_n \subset E_n$ such that the interval K_n defined by the same $s_n t_n$ restriction points and the restricting set G_n satisfies $m(J_n - K_n) < \epsilon/2^{n+1}$. Let $L_n = \bigcap_{j=1}^n K_j$, and use the closed set which is the intersection of the restricting sets of $K_1, \dots, K_n$ as its restricting set (the restricting sets all being raised to the same Euclidean dimensionality). Since $L_n, J_n - L_n$ are intervals, $L_n \subset K_n \subset J_n$ and m is finitely additive

$$(8.2) \quad m(J_n) = m(J_n - L_n) + m(L_n).$$

It can be seen readily that $J_n - L_n = J_n - \bigcap_{j=1}^n K_j \subset \bigcup_{j=1}^n (J_j - K_j)$, and hence from the finite additivity of m

$$(8.3) \quad m(J_n - L_n) \leq \sum_{j=1}^n m(J_j - K_j) < \sum_{j=1}^n \frac{\epsilon}{2^{j+1}} < \frac{\epsilon}{2} \quad \text{for all } n.$$

(3) It remains to show that there exists an integer n_0 such that $m(L_n) < \epsilon/2$ for $n \geq n_0$ by means of Theorem I. Let $a > 0$ be so chosen that for any interval disjoint from A_a , its measure is less than $\epsilon/2$. To show that $L_n \cap A_a = \emptyset$ for $n \geq n_0$ for some integer n_0 . Let $M_n = L_n \cap A_a$. Since $\{L_n\}$ is monotonically decreasing, so is $\{M_n\}$ and $\lim_{n \rightarrow \infty} M_n = \bigcap_{n=1}^{\infty} M_n \subset \bigcap_{n=1}^{\infty} J_n = \emptyset$. We claim that there exists an integer n_0 such that $M_n = \emptyset$ for $n \geq n_0$. Assume the contrary, then since $\{M_n\}$ is monotonically decreasing none of $\{M_n\}$ is empty. Let $f_n \in M_n$ and consider the sequence $\{f_n\}$. By Lemma 5, there exists a subsequence $\{f_{n_k}\} \subset \{f_n\}$ which converges to an element f_0 of A_a . To show that $f_0 \in M_{n_k}$ for all n_k , let n_{k_0} be arbitrarily fixed. Since $\{M_{n_k}\}$ is monotonically decreasing $f_{n_k} \in M_{n_{k_0}}$ for $n_k \geq n_{k_0}$. Then by the corollary to Lemma 5, there exists a subsequence $\{f_{n_{k_l}}\} \subset \{f_{n_k}\}$ which converges to an element f_0^* of $M_{n_{k_0}}$. For any $P \in Q$, the sequence of numbers $\{f_{n_{k_l}}(P)\}$ being a subsequence of $\{f_{n_k}(P)\}$ converges to $f_0(P)$. Thus $f_0^*(P) = f_0(P)$ on Q , and $f_0 \in M_{n_{k_0}}$. From the arbitrariness of the choice of n_{k_0} , $f_0 \in M_{n_k}$ for all n_k . Now since f_0 belongs to infinitely many M_n , $f_0 \in \limsup_{n \rightarrow \infty} M_n = \lim_{n \rightarrow \infty} M_n = \emptyset$. This is a contradiction. Therefore there must exist an integer n_0 such that $M_n = \emptyset$ for all $n \geq n_0$. Then by Theorem I $m(L_n) < \epsilon/2$ for $n \geq n_0$, and by (8.2), (8.3), $m(J_n) < \epsilon$ for $n \geq n_0$. This proves the countable additivity of m .
