ASYMPTOTIC BEHAVIOR OF SOLUTIONS OF ORDINARY DIFFERENCE EQUATIONS

BY
CHARLES V. COFFMAN⁽¹⁾

1. **Introduction.** This paper is concerned with the asymptotic behavior of solutions of ordinary difference equations with "almost constant coefficients," i.e., equations having the form

$$(1.1) \quad y(n+1) = Jy(n) + f(n, y(n)),$$

where y is a d -vector, J is a constant $d \times d$ matrix and $f(n, y)$ is a vector-valued function which is continuous in y for fixed n and becomes "small" in some sense as $(n, y) \rightarrow (\infty, 0)$. Systems of this type have been studied by Perron, among others; see for example [10]. Perron has also investigated the analogous problem of the asymptotic behavior of solutions of the differential equation

$$(1.2) \quad \frac{dy}{dt} = Jy + g(t, y),$$

where $g(t, y)$ is continuous in (t, y) and becomes "small" as $(t, y) \rightarrow (\infty, 0)$, cf. [9]. These two papers of Perron serve to illustrate the parallel which exists between the two problems. It is the purpose of this paper to present analogues for difference equations of several recent developments in the theory of the asymptotic behavior of solutions of the differential equation (1.2).

The first theorem below is the analogue for difference equations of a theorem of Hartman and Wintner [6, (*)] which deals with asymptotic integration of (1.2) on a logarithmic scale. The latter terminology derives from the fact that what is asserted is the following: corresponding to each eigenvalue λ of J , there exist solutions $y = y(t)$ of (1.2) satisfying

$$(1.3) \quad t^{-1} \log |y(t)| = \operatorname{Re} \lambda + o(1) \quad \text{as } t \rightarrow \infty,$$

where $|y|$ denotes the norm of the vector y . The analogue of (1.3) for the difference equation (1.1) is

$$(1.4) \quad |y(n)|^{1/n} = |\lambda| + o(1) \quad \text{as } n \rightarrow \infty.$$

It can be assumed that (1.1) can be written in the form

$$y^i(n+1) = J_i y^i(n) + f_i(n, y(n)), \quad i = 1, 2, 3,$$

Received by the editors November 8, 1962.

where $y = (y^1, y^2, y^3)$ and the absolute values of the eigenvalues of J_1, J_2 and J_3 are respectively less than, equal to, and greater than $|\lambda|$. Theorem 3.1 asserts that if y_0^1 and $y_0^2 \neq 0$ are given and if n_0 is sufficiently large, then (1.1) has a solution $y = y(n)$ such that

$$(1.5) \quad y^1(n_0) = y_0^1, \quad y^2(n_0) = y_0^2,$$

(1.4) holds, and $|y^i(n)| = o(|y^2(n)|)$ as $n \rightarrow \infty$ for $i = 1, 3$. Results of this type, both for differential equations [9, Satz 11] and for difference equations [10, Satz 11] have been proved by Perron. For the differential equations case, Hartman and Wintner, in the theorem mentioned above, have weakened Perron's condition

$$(1.6) \quad g(t, 0) \equiv 0, \quad |g(t, y_1) - g(t, y_2)| / |y_1 - y_2| \rightarrow 0 \text{ as } (t, y_1, y_2) \rightarrow (\infty, 0, 0)$$

on $g(t, y)$ in (1.2) to

$$(1.7) \quad |g(t, y)| / |y| \rightarrow 0 \text{ as } (t, y) \rightarrow (\infty, 0).$$

With the exception that Perron's uniqueness assertion fails under this weaker hypothesis, the conclusion of their theorem contains that of Satz 11, [9] of Perron. Similarly in [10, Satz 11], Perron requires the analogue of (1.6) for $f(n, y)$ in (1.1), i.e.,

$$(1.8) \quad f(n, 0) \equiv 0, \quad |f(n, y_1) - f(n, y_2)| / |y_1 - y_2| \rightarrow 0 \text{ as } (n, y_1, y_2) \rightarrow (\infty, 0, 0).$$

He proves, then, that there exists a unique solution of (1.1) satisfying (1.5) and (1.4). In Theorem 3.1 below, with the exception of the uniqueness assertion, the conclusion of Perron's theorem is obtained under the weaker assumption

$$(1.9) \quad |f(n, y)| / |y| \rightarrow 0 \text{ as } (n, y) \rightarrow (\infty, 0).$$

The conclusion of Theorem 3.1 is refined in Corollary 4.1. This assertion generalizes a result of Gelfond and Kubenskaya [4] which in turn refines a classical theorem concerning the linear, scalar equation of order d ,

$$(1.10) \quad x(n+d) + (a_1 + b_1(n))x(n+d-1) + \cdots + (a_d + b_d(n))x(n) = 0.$$

The result of Gelfond and Kubenskaya states that if the d roots $\lambda_1, \dots, \lambda_d$ of the characteristic polynomial

$$(1.11) \quad \lambda^d + a_1 \lambda^{d-1} + \cdots + a_d = 0$$

of the unperturbed part of (1.10) satisfy $|\lambda_1| < \cdots < |\lambda_d|$, and if the $|b_j(n)|$, $j = 0, \dots, d$ have a common positive majorant $\beta(n)$ satisfying

$$(1.12) \quad \lim_{n \rightarrow \infty} \beta(n) = 0,$$

$$(1.13) \quad \beta(n+1) \leq \beta(n),$$

$$(1.14) \quad \liminf_{n \rightarrow \infty} \beta(n+1)/\beta(n) = 1,$$

then to each i , $i = 1, \dots, d$, there corresponds a solution $x_i(n)$ of (1.10) such that

$$(1.15) \quad x_i(n+1)/x_i(n) = \lambda_i + O(\beta(n)).$$

In particular, Corollary 4.1 will be seen to imply that (1.14) can be weakened to

$$(1.16) \quad \liminf_{n \rightarrow \infty} \beta(n+1)/\beta(n) > \max_{1 \leq i < d} (|\lambda_i|/|\lambda_{i+1}|).$$

The proof given in [4] works without modification if (1.14) is replaced by (1.16)

In §§ 6 and 9 below, asymptotic formulae for the solutions of (1.1) are developed. Theorem 6.1 is the analogue of (†) in [6], the latter is a non linear version of a theorem first proved by Dunkel [1] for the linear case of (1.2). A refinement of Dunkel's theorem for the linear case is (**) [5]; another proof for the non-linear case has been given by Olech [8]. To my knowledge, the literature contains no theorem of this type for the difference equation (1.1) where J is allowed to have characteristic numbers and elementary divisors of arbitrary multiplicities. Gelfond and Kubenskaya have, as an immediate corollary of the theorem referred to above, that when $\sum^\infty \beta(n) < \infty$, then for each $i = 1, \dots, d$, there exists a solution $x = x_i(n)$ of (1.10) such that $x_i(n) = \lambda_i^n [1 + O(\sum_{n+1}^\infty \beta(n))]$ as $n \rightarrow \infty$. Theorem 6.1 or a theorem of Evgrabov [2], implies that if $\sum^\infty |b_i(n)| < \infty$, for $i = 1, \dots, d$, then for each i , (1.10) has a solution satisfying $x_i(n) = \lambda_i^n (1 + o(1))$, as $n \rightarrow \infty$. Evgrabov has proved the case of Theorem 6.1, where $f(n, y)$ is linear in y for each n , J is diagonal, and all of the eigenvalues of J are distinct, though not necessarily of distinct absolute value. Actually the case where J is diagonal but does not have distinct eigenvalues is easily reduced to the case treated by Evgrabov by a linear change of dependent variable, not affecting his condition on $f(n, y)$.

Theorems 9.1 and 9.2 also are analogues of theorems concerning differential equations (cf. (i), (ii) of [5]). In particular, the results of §9 contain a theorem of W. Ford [3] concerning the case $d = 2$ of (1.10); cf. §10.

§10 deals with applications of the theorems of §§6 and 9 to the scalar equation (1.10) and in particular to the second order case.

Apparently essential to the relaxation of (1.6) to (1.7) for the asymptotic integration of (1.2) on the logarithmic scale, and to the proof of the nonlinear analogue of Dunkel's theorem is some sort of topological argument, such as, for example, the principle embodied in the theorem of Ważewski [11]. As would be expected, a topological argument also seems essential to the proofs of the analogous theorems for difference equations. Due to the discrete nature of the independent variable in this case, there appears to be no natural analogue of Ważewski's theorem for difference equations. Adequate as a substitute in the cases treated here is Lemma 3.1, whose proof is based on an argument involving the mapping degree. The lemma is, in fact, equivalent to the Brouwer fixed point theorem.

2. Preliminary lemmas. This section contains several preliminary lemmas concerning two-dimensional systems of inequalities of the form

$$(2.1) \quad u(n+1) \leq \sigma u(n) + f(n)(u(n) + v(n)),$$

$$(2.2) \quad v(n+1) \geq \tau v(n) - f(n)(u(n) + v(n)).$$

It will be assumed that $f(n)$ is defined for $0, 1, \dots$, and is real and non-negative, that

$$(2.3) \quad \lim_{n \rightarrow \infty} f(n) = 0,$$

and that

$$(2.4) \quad 0 \leq \sigma < \tau.$$

LEMMA 2.1. *Let σ, τ be constants satisfying (2.4). Let $u(n)$ and $v(n)$ be non-negative functions of the integral variable n , defined for $n_0 \leq n \leq n^0$ and satisfying (2.1)–(2.2). Then, for any $\varepsilon > 0$, there exists an $N = N(\varepsilon)$, such that if $n_0 \geq N$ and $u(n_0) < \varepsilon v(n_0)$, then $v(n) > 0$ for $n_0 \leq n \leq n^0$ and*

$$(2.5) \quad u(n) < \varepsilon v(n)$$

for $n_0 \leq n \leq n^0$.

Proof. Choose $N(\varepsilon)$ so large that both $(1 + \varepsilon)f(n) < \tau$ and $(\sigma\varepsilon + f(n))(1 + \varepsilon)/(\tau - f(n))(1 + \varepsilon) < \varepsilon$ hold for all $n \geq N(\varepsilon)$. When $n_0 \geq N(\varepsilon)$, the conclusion follows for $n_0 \leq n \leq n^0$ by induction on n . If, for some n , $n_0 \leq n \leq n^0$, $v(n) > 0$, and (2.5) holds, then $v(n+1) \geq \tau v(n) - f(n)(1 + \varepsilon)v(n) > 0$ and one obtains

$$u(n+1)/v(n+1) \leq [\sigma u(n) + f(n)(u(n) + v(n))]/[\tau v(n) - f(n)(u(n) + v(n))],$$

$$u(n+1)/v(n+1) \leq [\sigma\varepsilon + f(n)(1 + \varepsilon)]/[\tau - f(n)(1 + \varepsilon)] < \varepsilon,$$

and so (2.5) holds for $n+1$.

It is clear from the proof just completed that when (2.3) is not assumed, the following variant of Lemma 2.1 will hold.

LEMMA 2.1'. *Let σ, τ , $u(n)$ and $v(n)$ be as in Lemma 2.1. Then for any $\varepsilon > 0$, there exists a $\delta = \delta(\varepsilon) > 0$ such that if (2.5) holds for $n = n_0$ and if $0 \leq f(n) \leq \delta(\varepsilon)$ for $n_0 \leq n \leq n^0$, then $v(n) > 0$ and (2.5) holds for $n_0 \leq n \leq n^0$.*

LEMMA 2.2. *Let σ, τ be constants satisfying (2.4). Let $u(n)$, $v(n)$ be defined and non-negative for $n \geq n_0$ and satisfy (2.1)–(2.2) and*

$$(2.6) \quad u(n) + v(n) \neq 0.$$

Either (α) $r(n) = u(n)/v(n)$ is defined for all sufficiently large n and

$$(2.7) \quad \lim_{n \rightarrow \infty} r(n) = 0,$$

or (β) $s(n) = v(n)/u(n)$ is defined for all sufficiently large n and

$$(2.8) \quad \lim_{n \rightarrow \infty} s(n) = 0.$$

Proof. Assume that (β) fails to hold. Then there exists an $\varepsilon > 0$ such that (2.5) holds for arbitrarily large values of n . Hence, by Lemma 2.1, $v(n) > 0$ for all sufficiently large values of n and (2.5) holds.

Let some number μ be chosen, so that $\sigma/\tau < \mu < 1$. Since (β) fails to hold, there is an N_0 so large that for all $n \geq N_0$, $v(n) > 0$, and, for some $\varepsilon > 0$, (2.5) holds, $\tau - f(n)(1 + \varepsilon) > 0$, and $(\sigma + f(n))/(\tau - f(n)(1 + \varepsilon)) < \mu$. It follows that $r(n + 1) \leq \mu r(n) + cf(n)$ for $n \geq N_0$, where $c > 0$. Upon iterating this inequality one obtains

$$(2.9) \quad r(n) \leq \mu^{n-m} r(m) + c \sum_{l=0}^{n-m-1} \mu^l f(n-l-1)$$

for $n > m \geq N_0$. Let $\phi(n)$ be a positive majorant for $f(n)$, defined for $n \geq N_0$, and assume that

$$(2.10) \quad \lim_{n \rightarrow \infty} \phi(n) = 0 \text{ and } \phi(n+1)/\phi(n) \geq \alpha > \sigma/\tau \text{ for } n \geq N_0.$$

It may be supposed that $\mu < \alpha$. From (2.9), one has

$$r(n) \leq \mu^{n-m} r(m) + c\alpha^{-1} \phi(n) \sum_{l=0}^{\infty} (\mu/\alpha)^l$$

for $n > m \geq N_0$. Thus

$$(2.11) \quad r(n) = O(\phi(n)).$$

This completes the proof of Lemma 2.2.

If (β) holds and if $1 > \mu > \sigma/\tau$, then for all sufficiently large n , $s(n+1) \geq \mu^{-1}s(n) - cf(n)$, where $c > 0$. Iterating this inequality yields $s(n+k) \geq \mu^{-k}[s(n) - c \sum_{l=1}^k \mu^l f(n+l-1)]$. Since $\mu < 1$, it follows from (1.8), on letting $k \rightarrow \infty$, that

$$(2.12) \quad s(n) \leq c \sum_{l=1}^{\infty} \mu^l f(n+l-1).$$

Thus if $\psi(n)$ is any positive majorant for $f(n)$ such that

$$\lim_{n \rightarrow \infty} \psi(n) = 0 \text{ and } \psi(n+1) \leq \psi(n),$$

then

$$(2.14) \quad s(n) = O(\psi(n)).$$

LEMMA 2.3. *Let the hypothesis of Lemma 2.2 hold and assume, in addition, that for some p , $1 \leq p < \infty$, $f(n) \in l^p$, i.e., $\sum_{n=1}^{\infty} |f(n)|^p < \infty$. Then if (α) holds, $\sum_{n=n_0}^{\infty} |r(n)|^p < \infty$ for some n_0 ; and if (β) holds then $\sum_{n=n_0}^{\infty} |s(n)|^p < \infty$, for some n_0 .*

Proof. In view of Minkowski's inequality, (2.9) and (2.12), it suffices to prove that if $f(n) \in l^p$, then $h(n) = \sum_{l=0}^{n-1} \mu^l f(n-l-1)$ and $g(n) = \sum_{l=1}^{\infty} \mu^l f(n+l-1)$ belong to l^p also. Write $g(n) = \sum_{l=n}^{\infty} \mu^{l-n+1} f(l)$ and let $t = 1 - 1/p$. By Hölder's inequality,

$$\begin{aligned} |g(n)|^p &= \left| \sum_{l=n}^{\infty} (\mu^{t(l-n+1)}) (\mu^{(l-n+1)/p}) f(l) \right|^p \\ &\leq \left(\sum_{l=n}^{\infty} \mu^{l-n+1} \right)^{tp} \left(\sum_{l=n}^{\infty} \mu^{l-n+1} |f(l)|^p \right). \end{aligned}$$

Hence

$$\begin{aligned} \sum_{n=1}^N |g(n)|^p &\leq \text{const.} \sum_{n=1}^N \sum_{l=n}^{\infty} \mu^{l-n+1} |f(l)|^p \\ &\leq \text{const.} \sum_{l=1}^{\infty} \sum_{n=1}^l \mu^{l-n+1} |f(l)|^p \\ &\leq \text{const.} \sum_{l=1}^{\infty} |f(l)|^p. \end{aligned}$$

If $h(n)$ is written as $h(n) = \sum_{l=0}^{n-1} \mu^{n-l-1} f(l)$ and if $t = 1 - 1/p$, then

$$\begin{aligned} |h(n)|^p &\leq \left(\sum_{l=0}^{n-1} \mu^{n-l-1} \right)^{tp} \left(\sum_{l=0}^{n-1} |f(l)|^p \right) \\ &\leq \text{const.} \sum_{l=0}^{n-1} \mu^{n-l-1} |f(l)|^p. \end{aligned}$$

The proof is completed as in the previous case.

The last two results of this section will concern the more general system

$$(2.15) \quad u(n+1) \leq \sigma(n)u(n) + f(n)(u(n) + v(n)),$$

$$(2.16) \quad v(n+1) \geq \tau(n)v(n) - f(n)(u(n) + v(n)),$$

where $f(n)$ is non-negative and satisfies (2.3) and $0 \leq \sigma(n) \leq \tau(n)$ for $n = 0, 1, \dots$.

LEMMA 2.4. Let $u(n)$ and $v(n)$ be defined and non-negative for all $n \geq n_0$, and satisfy (2.15)–(2.16), (2.6) and

$$(2.17) \quad 0 < K_0 \leq (u(n) + v(n))/(u(n+1) + v(n+1)) \leq K_1$$

for $n \geq n_0$. Put $v(n) = \tau(n) - \sigma(n)$ and assume that $\sum v(n)$ is divergent. Finally let

$$(2.18) \quad \lim_{0 \leq M < \infty} \left| \sum_{k=n}^{n+M} f(k) / \left(1 + \sum_{k=n}^{n+M} v(k) \right) \right| \rightarrow 0$$

as $n \rightarrow \infty$. Set $\zeta(n) = u(n)/(u(n) + v(n))$. Then $\lim_{n \rightarrow \infty} \zeta(n)$ exists and is zero or one. Also, to any δ, ε , $0 < \frac{1}{2}\varepsilon \leq \delta < \varepsilon < 1$, there corresponds an integer $N_0 = N_0(\delta, \varepsilon)$ such that if $n_0 \geq N_0$ and $\zeta(n_0) \leq \delta$, then

$$(2.19) \quad \zeta(n) < \varepsilon \text{ for all } n \geq n_0.$$

Proof. Upon multiplying (2.15) by $v(n)$ and (2.16) by $-u(n)$ and adding the resulting inequalities, one obtains

$$(u(n+1) + v(n+1))(u(n) + v(n))\Delta\zeta(n) \leq -v(n)(u(n) + v(n))^2\zeta(n)(1 - \zeta(n)) \\ + f(n)(u(n) + v(n))^2$$

and hence

$$\Delta\zeta(n) \leq -K_0v(n)\zeta(n)(1 - \zeta(n)) + K_1f(n),$$

where $\Delta\zeta(n) = \zeta(n+1) - \zeta(n)$. Let $c = \min(\frac{1}{2}K_0\delta(1 - \varepsilon), (\varepsilon - \delta))$. Choose $N_0 = N_0(\delta, \varepsilon)$ so that $f(n) < \frac{1}{2}K_1^{-1}(\varepsilon - \delta)$ and $\sum_{k=n}^{n+M} f(k) < cK_1^{-1}(1 + \sum_{k=n}^{n+M} v(k))$ for any integer $M \geq 0$ when $n \geq N_0$. Let $n_0 \geq N_0$, $\zeta(n_0) \leq \delta$, and suppose that there exists an $n_1 > n_0$ such that $\zeta(n_1) \geq \varepsilon$. It can be assumed that $\zeta(n) < \varepsilon$ for $n_0 \leq n < n_1$. Since $\Delta\zeta(n) \leq K_1f(n) < \frac{1}{2}(\varepsilon - \delta)$ for $n \geq N_0$, there exists an m , $n_0 \leq m < n_1$, such that $\zeta(n) \geq \frac{1}{2}\delta$ for $m \leq n \leq n_1$ and $\zeta(m) \leq \delta$. Then if $m \leq n < n_1$, $\zeta(n)(1 - \zeta(n)) \geq \frac{1}{2}\delta(1 - \varepsilon)$, so $\varepsilon - \delta \leq \zeta(n_1) - \zeta(m) \leq -\frac{1}{2}K_0\delta(1 - \varepsilon) \sum_{k=m}^{n_1-1} v(k) + K_1 \sum_{k=m}^{n_1-1} f(k)$ but

$$-\frac{1}{2}K_0\delta(1 - \varepsilon) \sum_{k=m}^{n_1-1} v(k) + K_1 \sum_{k=m}^{n_1-1} f(k) < c \leq \varepsilon - \delta,$$

hence a contradiction.

To complete the proof, it will be shown that if (2.19) holds for any $\varepsilon < 1$, for all large n , then $\limsup \zeta(n) = 0$ as $n \rightarrow \infty$. If $1 > b = \limsup \zeta(n) > 0$, then necessarily $\liminf \zeta(n) > 0$, for otherwise, $\zeta(n) < b/4$ would hold for arbitrarily large values of n , and hence, by the last part of the lemma $\zeta(n) < \frac{1}{2}b$ would hold for all sufficiently large n . It would follow then that $\zeta(n)(1 - \zeta(n)) \geq c_0 > 0$ for all sufficiently large n , hence $\Delta\zeta(n) \leq -c_0K_0v(n) + K_1f(n)$. This yields

$$\zeta(n+M) - \zeta(n) + c_0K_0 \sum_{k=n}^{n+M} v(k) \leq K_1 \sum_{k=n}^{n+M} f(k)$$

for any $M > 0$ for all sufficiently large n . In view of the divergence of $\sum v(k)$, this contradicts (2.18).

If, as $n \rightarrow \infty$,

$$(2.20) \quad v(n) \sim \text{const. } n^{-1} \text{ for some positive const.}$$

the following analogue of Lemma 2.3 holds for (2.15)–(2.16).,

LEMMA 2.5. Let $u(n)$ and $v(n)$ be defined, non-negative, and satisfy (2.15)–(2.16), (2.6) and (2.17) for $n \geq n_0$. Let $\tau(n) > \sigma(n) \geq 0$ for $n \geq 0$, and $v(n) = \tau(n) - \sigma(n)$ satisfy (2.20). Assume that for some p , $1 \leq p < \infty$

$$(2.21) \quad \sum_{n=n_0}^{\infty} n^{p-1} |f(n)|^p < \infty.$$

Then the conclusion of Lemma 2.4 holds and either

$$(2.22) \quad \sum_{n=n_0}^{\infty} n^{-1} |\zeta(n)|^p < \infty$$

or

$$(2.23) \quad \sum_{n=n_0}^{\infty} n^{-1} |1 - \zeta(n)|^p < \infty.$$

Proof. First it will be shown that the hypothesis of Lemma 2.4 is implied by the hypothesis of Lemma 2.5. It is only necessary to verify that (2.20) and (2.21) imply (2.18). By Hölder's inequality,

$$\sum_{k=n}^{n+M} f(k) \leq \left(\sum_{k=n}^{n+M} n^{-1} \right)^t \left(\sum_{k=n}^{n+M} n^{p-1} |f(n)|^p \right)^{1/p},$$

where $t = 1 - 1/p$, but

$$\left(\sum_{k=n}^{n+M} n^{-1} \right)^t \leq 1 + \sum_{k=n}^{n+M} n^{-1}.$$

Hence (2.18) follows from (2.20) and (2.21).

Suppose that $\zeta(n) \rightarrow 0$ as $n \rightarrow \infty$, then for sufficiently large n , $\zeta(n)$ satisfies

$$\Delta \zeta(n) \leq -K_2 n^{-1} \zeta(n) + K_1 f(n),$$

where $K_2 > 0$. For some $c > 0$ and for large n ,

$$n^{-c} \Delta n^c = n^{-c} ((n+1)^c - n^c) \leq K_2 n^{-1};$$

therefore

$$\Delta(n^c \zeta(n)) \leq K_1 n^c f(n)$$

for large n . Hence

$$\zeta(n) \leq (n_0/n)^c \zeta(n_0) + \sum_{k=n_0}^{n-1} (k/n)^c f(k)$$

for n_0 large and $n > n_0$. In view of Minkowski's inequality, (2.22) follows if it is shown that

$$(2.24) \quad \sum_{n=n_0+1}^{\infty} n^{-1} \left[\sum_{k=n_0}^{n-1} (k/n)^c f(k) \right]^p < \infty.$$

By Hölder's inequality,

$$\begin{aligned} \left[\sum_{k=n_0}^{n-1} (k/n)^c f(k) \right]^p &\leq \left[\sum_{k=n_0}^{n-1} (k/n)^c \right]^{p-1} \sum_{k=n_0}^{n-1} (k/n)^c |f(k)|^p \\ &\leq \text{const. } n^{p-1} \sum_{k=n_0}^{N-1} (k/n)^c |f(k)|^p. \end{aligned}$$

Therefore

$$\begin{aligned} \sum_{n=n_0+1}^N n^{-1} \left[\sum_{k=n_0}^{n-1} (k/n)^c f(k) \right]^p &\leq \text{const.} \sum_{k=n_0}^{N-1} |f(k)|^p k^c \sum_{n=k+1}^N n^{p-c-2} \\ &\leq \text{const.} \sum_{k=n_0}^{N-1} k^{p-1} |f(k)|^p, \end{aligned}$$

and (2.24) follows.

The proof of (2.23) when $\zeta(n) \rightarrow 1$, $n \rightarrow \infty$, is similar.

3. Logarithmic scale. In the system of ordinary difference equations

$$(3.1) \quad y(n+1) = Jy(n) + f(n, y(n)),$$

where y and f are d -vectors (with complex-valued components), let the $d \times d$ matrix J be in a Jordan canonical form, say, with g blocks. For $n = 0, 1, 2, \dots$, let the function $f(n, y)$ be defined and continuous in y for $|y| < c$, where c is some positive constant independent of n .

If $\lambda(1), \lambda(2), \dots, \lambda(g)$, with $|\lambda(1)| \leq |\lambda(2)| \leq \dots \leq |\lambda(g)|$, are the eigenvalues of the blocks of J , let the components of the vectors y and f be indexed so that (3.1) can be written as a system of scalar equations of the form

$$(3.1_{j1}) \quad y^{j1}(n+1) = \lambda(j)y^{j1}(n) + f^{j1}(n, y(n)),$$

$$(3.1_{jk}) \quad y^{jk}(n+1) = \lambda(j)y^{jk}(n) + y^{jk-1}(n) + f^{jk}(n, y(n)), \quad k = 2, \dots, h(j),$$

Let

$$j = 1, \dots, g.$$

$$(3.2) \quad \rho^1 < \rho^2 < \dots < \rho^f$$

denote the f distinct numbers among the $|\lambda(j)|$. Let some m , $1 \leq m \leq f$ be chosen. An integer j , $1 \leq j \leq g$, will be designated by $p = p(m)$, $q = q(m)$, or $r = r(m)$ according as $|\lambda(j)| < \rho^m$, $|\lambda(j)| = \rho^m$, or $|\lambda(j)| > \rho^m$.

In terms of the notation just introduced, define $L_{ma} = L_{ma}(y)$ for $1 \leq m \leq f$ and for $0 < a \leq 1$ by

$$(3.3) \quad L_{ma}(y) = \sum_q \sum_{k=1}^{h(q)} a^k |y^{qk}|.$$

Put $|y| = \sum_{j=1}^f L_{j1}$. The norm $|f|$ of the vector $f = f(n, y)$ will be defined as

$$|f| = \sum_{j=1}^q \sum_{k=1}^{h(j)} |f^{jk}|.$$

THEOREM 3.1. Let $f(n, y)$ satisfy

$$(3.4) \quad |f(n, y)|/|y| \rightarrow 0 \text{ as } (n, y) \rightarrow (\infty, 0).$$

Let

$$(3.5) \quad \rho = \rho^m < 1.$$

If η is any number such that $0 < \eta < 1$ then there exist positive numbers $\delta = \delta(\eta)$ and $N = N(\eta)$ such that for any set of $\sum h(p) + \sum h(q)$ numbers y_0^{pk} and y_0^{qk} satisfying

$$(3.6_1) \quad \sum_p \sum_{k=1}^{h(p)} |y_0^{pk}| \leq \eta \sum_q \sum_{k=1}^{h(q)} |y_0^{qk}|,$$

$$(3.6_2) \quad 0 < \sum_q \sum_{k=1}^{h(q)} |y_0^{qk}| < \delta,$$

there exists, for any $n_0 > N$, a solution $y = y_0(n)$ of (3.1), defined for $n \geq n_0$ and satisfying the incomplete set of initial conditions

$$(3.7_1) \quad y^{pk}(n_0) = y_0^{pk},$$

$$(3.7_2) \quad y^{qk}(n_0) = y_0^{qk},$$

and such that

$$(3.8) \quad \lim_{n \rightarrow \infty} |y_0(n)|^{1/n} = \rho.$$

Further, if $\rho > 0$, or more generally if $y_0(n)$ does not vanish identically for large n , then

$$(3.9) \quad L_j(y_0(n)) = o(L_m(y_0(n))) \quad \text{as } n \rightarrow \infty \text{ if } j \neq m.$$

The proof is facilitated by redefining $f(n, y)$ in the following manner:

For any $k > 0$, there exists, by (3.4), a positive number $\delta_0 = \delta_0(k)$, and a positive integer $N_0 = N_0(k)$ such that for $n \geq N_0$ and $|y| \leq \delta_0$, $|f(n, y)| < k|y|$. For some k , to be specified later, let $f(n, y)$ be redefined, for each $n \geq N_0$, outside of $|y| \leq \delta_0(k)$ so as to be continuous in y and satisfy

$$(3.10) \quad |f(n, y)| < k|y| \text{ for all } y,$$

and

$$(3.11) \quad f(n, y) \equiv 0 \text{ for } |y| \geq \Delta,$$

for some constant $\Delta > \delta_0$. Let (3.1') denote the equation (3.1) with f redefined as above. Because f is now defined for all y , for $n \geq N_0$, any solution of (3.1') beginning at some $n_0 \geq N_0$ exists for all $n \geq n_0$.

When $m = f$ there is only one possible $y_0(n)$, since in this case (3.7) forms a complete set of initial conditions. (Unique determination of solutions of (3.1') by initial conditions can fail in the sense that two solutions with distinct initial values at n_0 can coincide for $n \geq n_1 > n_0$, however, there can obviously be only one solution of (3.1') defined for $n \geq n_0$ and having a given set of initial values at n_0 .) Thus, until specified otherwise, it is to be assumed that $m < f$.

From (3.1' _{jk}) it follows that if $y = y(n)$ is a solution of (3.1') defined for $n \geq n_0 \geq N_0$, then for any a , $0 < a \leq 1$, and for $1 \leq i \leq f$, the following inequality holds

$$(3.12) \quad |L_{ia}(n+1) - \rho^i L_{ia}(n)| \leq a L_{ia}(n) + \sum_{j=q(i)} \sum_{k=1}^{h(j)} |f^{jk}(n, y(n))|,$$

where $L_{ia}(n) = L_{ia}(y(n))$. For $1 \leq i \leq f$, put

$$(3.13) \quad M_i(n) = M_{ia}(n) = \sum_{j=1}^{i-1} L_{ja}(n) \text{ and } N_i(n) = N_{ia}(n) = \sum_{j=1}^f L_{ja}(n).$$

From (3.2) and (3.12) follow the inequalities

$$(3.14_i) \quad M_i(n+1) \leq (\rho^{i-1} + a) M_i(n) + |f(n, y(n))|,$$

$$(3.15_i) \quad N_i(n+1) \geq (\rho^i - a) N_i(n) - |f(n, y(n))|.$$

Since

$$(3.16) \quad |y(n)| \leq a^{-d}(M_i(n) + N_i(n)),$$

in view of (3.10), these inequalities imply

$$(3.17_i) \quad M_i(n+1) \leq (\rho^{i-1} + a) M_i(n) + k a^{-d}(M_i(n) + N_i(n)),$$

$$(3.18_i) \quad N_i(n+1) \geq (\rho^i - a) N_i(n) - k a^{-d}(M_i(n) + N_i(n)).$$

Let $a > 0$ be chosen so that

$$(3.19_i) \quad \rho^{i-1} + a < \rho^i - a$$

for $i = m, m+1$. On applying Lemma 2.1' to the system (3.17_{m+1})–(3.18_{m+1}), it follows that, given $\varepsilon > 0$, if k is sufficiently small and if $n_0 \geq N_0(k)$, then $N_{m+1}(n_0) < \varepsilon N_{m+1}(n_0)$ implies $N_{m+1}(n) > 0$ for $n \geq n_0$, and

$$(3.20) \quad M_{m+1}(n) > \varepsilon N_{m+1}(n)$$

for $n \geq n_0$.

The following simple topological lemma will be used in proving the existence of the solution $y_0(n)$.

LEMMA 3.1. *Let y be a d -vector and let A be a nonsingular $d \times d$ matrix. Let the d -vector valued function $g(y)$ be defined and continuous for all y , and satisfy*

$$g(y) = 0 \text{ for } |y| \geq \gamma,$$

for some positive constant γ . Then the mapping of the y -space into itself given by

$$(3.21) \quad y_1 = Ay_0 + g(y_0)$$

is onto.

Proof. Let $F_t(y) = Ay + tg(y)$, $0 \leq t \leq 1$. Let y_{10} be arbitrary, and consider the mapping degree $a[y_{10}, F_t]$ of F_t at y_{10} , as defined, for example, in [7]. By Theorem 5 and the remark at the end of §3 of [7], $a[y_{10}, F_0] = \pm 1$, hence $a[y_{10}, F_1] = \pm 1$ and it follows from the result just referred to that there exists a y_0 such that $y_{10} = Ay_0 + g(y_0)$.

Let y_0^{rk} and y_0^{qk} be given, satisfying (3.6₁) for some η , $0 < \eta < 1$, and (3.6₂) (with δ to be specified). Let $n_0 \geq N_0(k)$, and let $y(n, y_0^{rk})$ denote the solution of (3.1') satisfying (3.7₁), (3.7₂) and

$$y^{rk}(n_0) = y_0^{rk}.$$

The mapping of the $\Sigma h(r)$ -dimensional space of variables y^{rk} into itself given by

$$y_1^{rk} = y^{rk}(n_0 + l, y_0^{rk})$$

has, for any $l > 0$, the form (3.21), and because of (3.2) and (3.11), satisfies the hypothesis of Lemma 3.1. It follows that for each $l > 0$, there exists a solution of (3.1') satisfying (3.7₁) and (3.7₂) and with

$$(3.22) \quad y^{rk}(n_0 + l) = 0.$$

For each $l > 0$, let one such solution be chosen and denoted $y = y_l(n)$.

The auxiliary functions $M_{m+1}(n)$ and $N_{m+1}(n)$ associated with the solution $y_l(n)$ must satisfy

$$(3.23) \quad M_{m+1}(n) \geq \varepsilon N_{m+1}(n)$$

for $n_0 \leq n \leq n_0 + l$. For if (3.23) failed to hold for some n on this range, the by the choice of k , (3.20) would hold at $n = n_0 + l$, contradicting (3.22). From (3.17_{m+1}) and (3.23)

$$M_{m+1}(n+1) \leq (\rho^m + a + ka^{-d}(1 + 1/\varepsilon))M_{m+1}(n),$$

for $n_0 \leq n \leq n_0 + l$. It may be supposed that k and a are so small that

$$v = \rho^m + a + ka^{-d}(1 + 1/\varepsilon) < 1.$$

Then from

$$(3.24) \quad M_{m+1}(n) \leq v^{n-n_0} M_{m+1}(n_0)$$

for $n_0 \leq n \leq n_0 + l$ and (3.16), it follows that $|y_l(n)| \leq v^{n-n_0} a^{-d}(1 + 1/\varepsilon) M_{m+1}(n_0)$, for $n_0 \leq n \leq n_0 + l$. But $M_{m+1}(n_0) \leq (1 + \eta) \sum |y_0^{qk}|$, by (3.6₁). Thus $\delta = \delta(\eta)$ is chosen so that $a^{-d}(1 + 1/\varepsilon)(1 + \eta)\delta < \delta_0$, then, if $y(n) = y_l(n)$,

$$(3.25) \quad |y(n)| < \delta_0,$$

for $n_0 \leq n \leq n_0 + l$.

From (3.25), it follows that there exists a subsequence of the $y_l(n)$ (which after renumeration can be supposed to be the full sequence) such that

$$y_0(n) = \lim_{l \rightarrow \infty} y_l(n)$$

exists for each $n \geq n_0$. The auxiliary functions $M_{m+1}(n)$ and $N_{m+1}(n)$ associated with $y_0(n)$ satisfy (3.23) and (3.24) for all $n \geq n_0$, and (3.25) holds for $y(n) = y_0(n)$, for all $n \geq n_0$. The latter assertion implies that $y_0(n)$, which is certainly a solution of (3.1'), is indeed a solution of the original equation (3.1). The relations (3.16), (3.23) and (3.24), for all $n \geq n_0$ imply $y_0(n) \rightarrow 0$ as $n \rightarrow \infty$. This in turn implies that $|f(n, y_0(n))| \leq h(n)(M_{m+1}(n) + N_{m+1}(n))$, where $h(n) \rightarrow 0$ as $n \rightarrow \infty$. Replacing $|f(n, y_0(n))|$ in (3.14_m), (3.15_m) by the term on the right in the above inequality and applying Lemma 2.2 yields

$$(3.26) \quad N_{m+1}(n) = o(M_{m+1}(n)) \quad \text{as } n \rightarrow \infty$$

provided $y_0(n) \neq 0$ for $n > n_0$. This completes the proof of (3.9) in case $m = 1$.

Suppose $m > 1$ and let $M_m(n), N_m(n)$ be the auxiliary functions associated with a solution of (3.1') satisfying (3.7) and with the initial conditions subject to (3.6₁). Then $M_m(n_0) \leq \eta a^{-d} L_{ma}(n_0)$ and hence

$$(3.27) \quad M_m(n) \leq \eta a^{-d} N_m(n)$$

for $n = n_0$. $M_m(n)$ and $N_m(n)$ satisfy (3.17_m)–(3.18_m) and a is such that (3.19_m) holds. By Lemma 2.1', k can be chosen so small that $n_0 \geq N(k)$ and (3.27) for $n = n_0$ imply that $N_m(n)$ does not vanish for $n \geq n_0$ and that (3.27) holds for $n \geq n_0$, since $N_m(n_0) \neq 0$ by (3.6₂).

If $1 < m < f$, let $y_0(n)$ be as above; if $m = f(> 1)$, let $y_0(n)$ be the solution of (3.1') determined by (3.6₁). It is easy to see that in the latter case, for n_0 large and δ small, $y_0(n)$ satisfies (3.25), and $y_0(n) \rightarrow 0$ as $n \rightarrow \infty$. The solution $y_0(n)$ of (3.1) satisfies (3.7) so $y_0(n)$ does not vanish and the associated auxiliary functions $M_m(n)$ and $N_m(n)$ satisfy (3.27) for $n \geq n_0$. As before, $|f(n, y_0(n))|$ in (3.14_m)–(3.15_m) can be replaced by $h(n)(M_m(n) + N_m(n))$, where $h(n) \rightarrow 0$ as $n \rightarrow \infty$, and Lemma 2.1 applied to give

$$(3.28) \quad M_m(n) = o(N_m(n)) \quad \text{as } n \rightarrow \infty.$$

The relations (3.26) and (3.28) together if $m < f$, or (3.28) alone if $m = f(> 1)$, yield (3.9). Of course (3.9) is vacuous if $f = 1$.

Since $y_0(n) \rightarrow 0$ as $n \rightarrow \infty$, from (3.4), (3.9) and (3.12), one has, for large n

$$L_{ma}(n+1)/L_{ma}(n) \leq \rho + 2a.$$

For some positive constant c_0 ,

$$L_{ma}(n) \leq c_0(\rho + 2a)^n \quad \text{for } n \geq n_0,$$

and this implies that

$$\limsup_{n \rightarrow \infty} |L_{ma}(n)|^{1/n} \leq \rho + 2a.$$

Since

$$|y_0(n)| \leq a^{-d}(1 + o(1))L_{ma}(n) \text{ as } n \rightarrow \infty,$$

$$\limsup_{n \rightarrow \infty} |y_0(n)|^{1/n} \leq \limsup_{n \rightarrow \infty} |L_{ma}(n)|^{1/n},$$

and since a can be taken arbitrarily small this implies

$$\limsup_{n \rightarrow \infty} |y_0(n)|^{1/n} \leq \rho.$$

When $\rho > 0$, the inequality

$$L_{ma}(n+1)/L_{ma}(n) \geq \rho - 2a$$

leads in a similar way to

$$\liminf_{n \rightarrow \infty} |y_0(n)| \geq \rho.$$

This proves (3.8).

4. A refinement. Let $y_0(n)$ be a nonvanishing solution of (3.1) satisfying (3.9) (and hence (3.8)). From the proof just completed, it follows that there exists a $\nu, \rho^m < \nu < 1$, and a constant K such that $|y_0^n(n)| \leq K\nu^n$ for $n \geq n_0$. Put

$$h(n) = \text{lub}_{0 < |y| \leq K\nu^n} |f(n, y)|/|y|.$$

It readily follows from (3.4) that $h(n) \rightarrow 0$ as $n \rightarrow \infty$. Let $\phi(n)$ and $\psi(n)$ be positive majorants for $h(n)$ satisfying respectively

$$(4.1) \quad \lim_{n \rightarrow \infty} \phi(n) = 0 \quad \text{and} \quad \liminf_{n \rightarrow \infty} \phi(n+1)/\phi(n) = a > \rho$$

and

$$(4.2) \quad \lim_{n \rightarrow \infty} \psi(n) = 0 \quad \text{and} \quad \psi(n+1) \leq \psi(n) \quad \text{for all } n \geq 0.$$

The assertion (3.9) of Theorem 3.1 can be refined as follows.

COROLLARY 4.1. *If $y_0(n)$ does not vanish for $n \geq n_0$, then for $j < m$*

$$(4.3) \quad L_j(n)/L_m(n) = O(\psi(n)) \quad \text{as } n \rightarrow \infty,$$

and for $j > m$

$$(4.4) \quad L_j(n)/L_m(n) = O(\phi(n)) \quad \text{as } n \rightarrow \infty.$$

This result follows easily from the proof of Theorem 3.1 and the estimates (2.11) and (2.14).

5. A converse of Theorem 3.1. As a partial converse of Theorem 3.1, one has

THEOREM 5.1. *Let $f(n, y)$ be as in Theorem 3.1. Let $y = y(n)$ ($\neq 0$) for large n be a solution of (3.1) defined for all sufficiently large n and such that*

$$(5.1) \quad y(n) \rightarrow 0 \quad \text{as } n \rightarrow \infty,$$

then there is an integer m_0 , $1 \leq m_0 \leq f$, such that $\rho = \rho^{m_0} \leq 1$, and (3.8) and (3.9) hold with $m = m_0$.

Proof. Consider the case $f > 1$. Choose a (> 0) so small that Lemma 2.2 is applicable to (3.14 _{m})–(3.15 _{m}). Applying the lemma, one concludes that for each $m = 1, \dots, f$, the auxiliary functions $M_m(n)$ and $N_m(n)$ associated with $y(n)$ satisfy, as $n \rightarrow \infty$, either

$$(5.2_1) \quad M_m(n) = o(N_m(n))$$

or

$$(5.2_2) \quad N_m(n) = o(M_m(n)).$$

Let m_0 be either the largest integer for which (5.2₁) holds or 1 if (5.2₁) holds for no value of m . Then, the pair of relations (5.2₁) for m_0 and (5.2₂) for $m_0 + 1$ if $f > m_0 > 1$, the relation (5.2₂) for $m_0 + 1$ if $m_0 = 1$, or the relation (5.2₁) for m_0 if $m_0 = f$, implies (3.9). As in the proof of Theorem 2.1, (3.9) implies (3.8) and (3.8), (5.1) for $m = m_0$ imply $\rho^{m_0} \leq 1$.

The case $f = 1$ is trivial.

6. Asymptotic formulae. Let some m , $1 \leq m \leq f$, be chosen. Let h_* denote the maximum multiplicity of the elementary divisors of J , the corresponding eigenvalues of which have absolute value ρ^m . In terms of the notations and conventions of §3,

$$(6.1) \quad h_* = \max_q h(q).$$

The main result of this section is the following

THEOREM 6.1. *Let m , $1 \leq m \leq f$, be such that $\rho = \rho^m$ satisfies*

$$(6.2) \quad 0 < \rho < 1.$$

Let h_0 be any number satisfying

$$(6.3) \quad h_* \leq h_0,$$

and let j_0 be some integer such that

$$(6.4) \quad 0 \leq j_0 < h_*$$

For each $n \geq 0$ let $f(n, y)$ be defined and continuous in y for $|y| \leq \text{const.}$ Let there exist, for each $n \geq 0$, a scalar function $\phi(n, r)$, defined and continuous in r for $|r| \leq \text{const.}$, and having the following properties

$$(6.5) \quad \phi(n, r) \text{ is nondecreasing in } r \text{ for each } n,$$

$$(6.6) \quad \sum \rho^{-n} n^{h_0 - j_0 - 1} \phi(n, \text{const.} n^{j_0} \rho^n) < \infty \text{ for every } \text{const.} > 0,$$

and such that

$$(6.7) \quad |f(n, y)| \leq \phi(n, |y|).$$

For each q , let $l(q)$ and $k(q)$ denote the least and greatest integers, if any, satisfying

$$(6.8) \quad 1 \leq l(q) \leq k(q) \leq \min(h(q), h_0 - j_0), \text{ and } h(q) - l(q) \leq j_0.$$

Let a set of numbers c^{qk} , where $l(q) \leq k \leq k(q)$, be given, and not all 0. Then there exists a solution $y = y(n)$ of (3.1), defined for all large n , and satisfying the asymptotic formula

$$(6.9_1) \quad y^{jk}(n) = o(n^{1-h_0+j_0}\rho^n) \quad \text{if } j \neq q,$$

and

$$(6.9_2) \quad y^{qk}(n) = \sum_{i=l(q)}^{k(q)} c^{qi} C_{n,k-i} \lambda^{n-k+i}(q) + o(n^{k-h_0+j_0}\rho^n),$$

where $C_{nk} = n! / k!(n-k)!$ is the binomial coefficient.

In particular, the hypothesis of the theorem is satisfied if (6.7) holds for some $\phi(n, r)$ having the form

$$(6.10) \quad \phi(n, r) = \psi(n)r,$$

where

$$(6.11) \quad \sum n^{h_0-1} \psi(n) < \infty.$$

For convenience in the proof it will be assumed that for all $n \geq 0$, $f(n, y)$ is defined and continuous for all y , and that $\phi(n, r)$ is defined, continuous, and monotone in r for all $r > 0$. It will be clear from the proof that this involves no loss of generality.

Let $y^j = (y^{j1}, \dots, y^{jh(j)})$, and $f^j(n, y) = (f^{j1}(n, y), \dots, f^{jh(j)}(n, y))$ for $j = 1, \dots, g$, (2.1) can then be written

$$(6.12_j) \quad y^j(n+1) = J(j)y^j(n) + f^j(n, y(n)), \quad j = 1, \dots, g,$$

where $J(j)$ is the j th block of J belonging to the eigenvalue $\lambda(j)$.

First the system will be transformed by a linear change of variable $y(n) = M(n)z(n)$

so as to diagonalize the linear part of (6.12_j). The change of variables will be made in two steps. Let $w^j(n) = (w^{j1}(n), \dots, w^{jh(j)}(n))$, $j = 1, \dots, g$ be defined by

$$(6.13_j) \quad y^j(n) = w^j(n) \quad \text{if } j \neq q,$$

$$(6.13_q) \quad y^q(n) = (J(q))^n \lambda^{-n}(q) w^q(n).$$

Component-wise (6.13) takes the form

$$(6.13_{qk}) \quad y^{qk}(n) = \sum_{i=1}^k C_{n,k-i} \lambda^{-k+i}(q) w^{qi}(n).$$

It is immediate from (6.13_q) that (6.12_q) is thus transformed to

$$(6.14_q) \quad w^q(n+1) = \lambda(q) w^q(n) + \lambda^{n+1}(q) (J(q))^{-n-1} f^q(n, y(n)).$$

The second step is the following, let

$$(6.15) \quad w^{jk}(n) = n^{1-\beta} z^{jk}(n), \quad k = 1, \dots, h(j) \quad \text{if } j \neq q,$$

$$(6.16) \quad w^{qk}(n) = n^{k-\beta} z^{qk}(n) \quad \text{if } k < l(q) \text{ or } k > k(q),$$

$$(6.17) \quad w^{qk}(n) = z^{qk}(n) \quad \text{if } l(q) \leq k \leq k(q),$$

where $\beta = h_0 - j_0$. The transformed system has the form

$$(6.18) \quad z^j(n+1) = (n/(n+1))^{1-\beta} J(j) z^j(n) + g^j(n, z(n)), \quad j \neq q,$$

$$(6.19) \quad z^{qk}(n+1) = (n/(n+1))^{k-\beta} \lambda(q) z^{qk}(n) + g^{qk}(n, z(n)), \quad \text{if } k < l(q) \text{ or } k > k(q),$$

$$(6.20) \quad z^{qk}(n+1) = \lambda(q) z^{qk}(n) + g^{qk}(n, z(n)), \quad \text{if } l(q) \leq k \leq k(q).$$

If $j \neq q$, $g^j(n, z) = (1/(n+1))^{1-\beta} f^j(n, M(n)z)$. The k th component of the vector $(\lambda(q))^{n+1} (J(q))^{-n-1} f^q(n, y)$ is $\sum_{i=1}^k (-1)^{k-i} C_{k-i+n} \lambda^{k-i}(q) f^{qi}(n, y)$, so upon observing that $C_{k-i+n} = O(n^{k-i})$ as $n \rightarrow \infty$, it follows easily that

$$|g^{qk}(n, z)| \leq \text{const.} \left(\sum_{i=1}^k n^{k-i} |f^{qi}(n, M(n)z)| \right) \quad \text{if } l(q) \leq k \leq k(q) \text{ and}$$

$$|g^{qk}(n, z)| \leq \text{const.} \left(\sum_{i=1}^k n^{\beta-i} |f^{qi}(n, M(n)z)| \right) \quad \text{if } k < l(q) \text{ or } k > k(q).$$

Since $k(q) \leq \beta$, one has

$$(6.21) \quad |g(n, z)| \leq \text{const.} n^{\beta-1} |f(n, M(n)z)|.$$

Notice, however, that for $l(q) \leq k \leq k(q)$,

$$(6.21') \quad |g^{qk}(n, z)| \leq \text{const.} n^{k-1} |f(n, M(n)z)|.$$

Let $s(q, k)$ be defined for $1 \leq k \leq h(q)$, as follows, $s(q, k) = 0$ if $l(q) \leq k \leq k(q)$, $s(q, k) = k - \beta$ otherwise. Using (6.5), one obtains for each q , for $k, i = 1, \dots, h(q)$, $k - i + s(q, i) \leq j_0$. Since $C_{n,k-i} = O(n^{k-i})$, as $n \rightarrow \infty$, combining (6.16)–(6.17)

with (6.13_{qk}) yields

$$\sum_q \sum_{k=1}^{h(q)} |y^{qk}| \leq \text{const. } n^{j_0} |z|.$$

The formulae (6.13_j) and (6.15), together with the above imply

$$(6.22) \quad |M(n)z| \leq \text{const. } n^{j_0} |z|.$$

Let c_0 and c_1 be the constants of (6.21) and (6.22), respectively. Let

$$(6.23) \quad \psi(n, r) = c_0 n^{\beta-1} \phi(n, c_1 n^{j_0} r),$$

by (6.21) and (6.22)

$$(6.24) \quad |g(n, z)| \leq \psi(n, |z|),$$

and by (6.21') and (6.22)

$$(6.25) \quad |g^{qk}(n, z)| \leq n^{k-\beta} \psi(n, |z|), \quad \text{if } l(q) \leq k \leq k(q).$$

Let two numbers K_0 and K_1 be given, with

$$(6.26) \quad 0 < K_0 < \sum |c^{qk}| < K_1.$$

For all $n \geq 0$, redefine $g(n, z)$ for $|z| < K_0 \rho^n$ and for $|z| > K_1 \rho^n$ so as to satisfy

$$(6.27) \quad |g(n, z)| \leq \psi(n, K_1 \rho^n),$$

and

$$(6.28) \quad g(n, z) = 0 \text{ if } |y| \geq 2K_1 \rho^n \text{ or if } |y| \leq \frac{1}{2} K_0 \rho^n.$$

Let (6.18')–(6.19')–(6.20') denote the system (6.18)–(6.19)–(6.20) with $g(n, z)$ redefined as above. With each solution $z(n)$, of the redefined system, will be associated auxiliary functions $u(n)$, $v(n)$ and $w(n)$ defined as follows

$$(6.29) \quad u(n) = M_{ma}(n) + \sum_q \sum_{k > k(q)} |z^{qk}(n)|,$$

$$(6.30) \quad v(n) = \sum_q \sum_{k=l(q)}^{k=k(q)} |z^{qk}(n)|,$$

$$(6.31) \quad w(n) = N_{m+1a}(n) + \sum_q \sum_{k < l(q)} |z^{qk}(n)|,$$

where $a > 0$ and M_{ma} and N_{ma} are defined by (3.13). One has thus $|z(n)| \leq a^{-d}(u(n) + v(n) + w(n))$. The function $g(n, z)$, when redefined to satisfy (6.27) and (6.28), satisfies

$$|g(n, z)|/|z| \leq 2K_0^{-1} \rho^{-n} \psi(n, K_1 \rho^n).$$

Put

$$(6.32) \quad \bar{\psi}(n) = 2a^{-d}K_0^{-1}\rho^{-n}\psi(n, K_1\rho^n).$$

Upon observing that $k - \beta \leq -1$ when $k < l(q)$ and ≥ 1 when $k > k(q)$, it follows from (6.18')–(6.19')–(6.20'), provided a is sufficiently small, that $u(n)$, $v(n)$ and $w(n)$ satisfy

$$(6.33) \quad u(n+1) \leq (n/(n+1))\rho u(n) + \bar{\psi}(n)(u(n) + v(n) + w(n)),$$

$$(6.34) \quad |v(n+1) - \rho v(n)| \leq \bar{\psi}(n)(u(n) + v(n) + w(n)),$$

$$(6.35) \quad w(n) \geq ((n+1)/n)\rho w(n) - \bar{\psi}(n)(u(n) + v(n) + w(n)).$$

Put

$$(6.36_1) \quad \bar{u}_1(n) = u(n), \quad \bar{v}_1(n) = v(n) + w(n),$$

$$(6.36_2) \quad \bar{u}_2(n) = u(n) + v(n), \quad \bar{v}_2(n) = w(n),$$

$$(6.37_1) \quad \sigma_1(n) = (n/(n+1))\rho, \quad \tau_1(n) = \rho,$$

$$(6.37_2) \quad \sigma_2(n) = \rho, \quad \tau_2(n) = (n+1/n)\rho.$$

From (6.33)–(6.34)–(6.35), one obtains

$$(6.38_i) \quad \bar{u}_i(n+1) \leq \sigma_i(n)\bar{u}_i(n) + \bar{\psi}(n)(\bar{u}_i(n) + \bar{v}_i(n)),$$

$$(6.39_i) \quad \bar{v}_i(n+1) \geq \tau_i(n)\bar{v}_i(n) - \bar{\psi}(n)(\bar{u}_i(n) + \bar{v}_i(n)),$$

for $i = 1, 2$. It follows from (6.32), (6.34), and (6.7) that $\sum \bar{\psi}(n) < \infty$; (6.37_i) implies that $\sigma_i(n) < \tau_i(n)$ and that $\sum [\tau_i(n) - \sigma_i(n)]$ is divergent, for $i = 1, 2$. Since $\rho > 0$, the proof of Theorem 3.1 implies the existence of an integer N_0 and constants L_0, L_1 ($0 < L_0 < L_1$) such that if $n_0 \geq N_0$ and if $M_m(n_0) = 0$, i.e., if

$$(6.40) \quad z^{pk}(n_0) = 0, \quad k = 1, \dots, h(p),$$

but $z(n_0) \neq 0$, then $z(n)$ does not vanish for $n \geq n_0$ and, for all $n \geq n_0$,

$$L_0 < (M_m(n+1) + N_m(n+1))/(M_m(n) + N_m(n)) < L_1.$$

This implies similar inequalities for pairs, $\bar{u}_i(n)$, $\bar{v}_i(n)$ associated with a solution $z(n)$ satisfying (6.40). It will be assumed, in fact, that L_0 and L_1 are such that if $n \geq n_0$, then for such pairs

$$(6.41) \quad L_0 < (\bar{u}_i(n+1) + \bar{v}_i(n+1))/(\bar{u}_i(n) + \bar{v}_i(n)) < L_1$$

for $i = 1, 2$. Let ε , $0 < \varepsilon < 1$, be given and choose $N_1 \geq N_0$, by Lemma 2.4, so that if $i = 1$ or 2 , $n_0 \geq N_1$, $\bar{u}_i(n)$ and $\bar{v}_i(n)$ are defined for $n \geq n_0$, and satisfy (6.38_i), (6.39_i) and (6.41), and if $\bar{u}_i(n_0) < \frac{1}{2}\varepsilon_i(\bar{u}_i(n_0) + \bar{v}_i(n_0))$, then

$$(6.42_i) \quad \bar{u}_i(n) < \varepsilon_i(\bar{u}_i(n) + \bar{v}_i(n))$$

for $n \geq n_0$, where $\varepsilon_1 = \frac{1}{2}\varepsilon_2 = \frac{1}{2}\varepsilon$.

Let $n_0 \geq N_1$ be fixed. By Lemma 2.1 there exists, for each $v \geq n_0$, a solution $z_v(n)$ satisfying (6.40)

$$(6.43) \quad z^{qk}(n_0) = 0, \quad k > k(q),$$

$$(6.44) \quad z^{qk}(v) = c^{qk}\lambda^v(q), \quad l(q) \leq k \leq k(q)$$

and

$$(6.45) \quad z^{jk}(v) = 0 \text{ if } j = r, \text{ or if } k < l(q).$$

The auxiliary functions $\bar{u}_i(n), \bar{v}_i(n)$, $i = 1, 2$, satisfy (6.41) for $n \geq n_0$, hence, since $\bar{u}_1(n_0) = 0$, (6.42₁) holds, for $n \geq n_0$. On the other hand, $\bar{v}_2(v) = 0$, so it must be the case that

$$(6.46) \quad \bar{u}_2(n) \geq \varepsilon(\bar{u}_2(n) + \bar{v}_2(n)),$$

for $n_0 \leq n < v$. The relations (6.42) and (6.46) for $n_0 \leq n < v$, imply, if ε is sufficiently small,

$$(6.47) \quad u(n) \leq \frac{1}{2}\delta v(n) \text{ and } w(n) \leq \frac{1}{2}\delta v(n)$$

for $n_0 \leq n \leq v$, where $\delta = \delta(\varepsilon) > 0$. The inequalities (6.47), combined with (6.34), yield,

$$(6.48) \quad |v(n+1) - \rho v(n)| \leq \bar{\psi}(n)(1 + \delta)v(n),$$

for $n_0 \leq n \leq v$. If n is on the latter range, (6.48), (6.44) and (6.25) imply

$$(6.49) \quad K_0 L^{-1} < \rho^{-n} v(n) < K_1 L$$

where $L = \exp(\text{const.} \sum_{n=n_0}^{\infty} \bar{\psi}(n))$, the const. (> 0) depending only on ρ , δ , and a bound for $\bar{\psi}(n)$. The relations (6.47) and (6.49) imply in particular that $z_v(n_0)$ is bounded independently of v . From (6.20), (6.25) and (6.49) one has, if $l(q) \leq k \leq k(q)$,

$$|z_v^{qk}(n+1) - \lambda(q)z_v^{qk}(n)| \leq n^{k-\beta} \bar{\psi}(n)(1 + \delta)K_1 L \rho^n,$$

for $n_0 \leq n \leq v$. It follows that

$$\begin{aligned} |\lambda^{n-v}(q)z_v^{qk}(v) - z_v^{qk}(n)| &\leq \sum_{i=1}^{v-1} \rho^{-i+n-1} |z_v^{qk}(i+1) - \lambda(q)z_v^{qk}(i)| \\ &\leq \rho^{n-1} K_1 L (1 + \delta) \sum_{i=n}^{\infty} i^{k-\beta} \bar{\psi}(i). \end{aligned}$$

Because of (6.44) this yields

$$(6.50) \quad |z_v^{qk}(n) - c^{qk}\lambda^n(q)| \leq \rho^{n-1}K_1L(1+\delta) \sum_{i=n}^{\infty} i^{k-\beta}\bar{\psi}(i),$$

if $n_0 \leq n \leq v$, for $l(q) \leq k \leq k(q)$.

Continuous dependence on initial conditions for solutions of (6.18')–(6.19')–(6.20') and the boundedness of $z_v(n_0)$ for $v \geq n_0$ implies the existence of an increasing sequence of integers $v(k)$ such that

$$(6.51) \quad z(n) = \lim_{k \rightarrow \infty} z_{v(k)}(n)$$

exists for each $n \geq n_0$. The function $z(n)$ defined by (6.51) is a solution of (6.18')–(6.19')–(6.20') and the associated auxiliary functions $u(n)$, $v(n)$ and $w(n)$ are the limits of the respective auxiliary functions associated with the $z_{v(k)}(n)$. It follows that the auxiliary functions for $z(n)$ satisfy (6.47) for all $n \geq n_0$. In view of the definitions (6.36₁), (6.36₂), it follows, on applying Lemma 2.4 to the systems (6.38_i)–(6.39_i), $i = 1, 2$, that

$$(6.52) \quad u(n) = o(v(n)), \quad w(n) = o(v(n)), \quad \text{as } n \rightarrow \infty.$$

Finally (6.50), for each $v \geq n_0$, implies that $z(n)$ satisfies

$$(6.53) \quad z^{qk}(n) = c^{qk}(\lambda(q))^n + o(n^{k-\beta}\rho^n), \quad \text{as } n \rightarrow \infty,$$

for $l(q) \leq k \leq k(q)$. The latter relation, together with (6.52) and (6.26) imply that for large n , $K_0 < \rho^{-n}|z(n)| < K_1$, so that $z(n)$ is, for large n , a solution of the original system (6.18)–(6.19)–(6.20).

It readily follows from (6.52), (6.53) and the definition of $M(n)$, that the solution $y(n) = M(n)z(n)$ of (6.12) satisfies (6.9).

7. The linear case. The condition on $f(n, y)$ in Theorem 6.1 is essentially invariant under a change of dependent variable of the form $y(n) = Ay(n)$, where A is a nonsingular constant matrix. Hence, to check the condition it is not necessary to have J in a Jordan normal form. If however J is in such a form, and in particular when $f(n, y)$ is linear in y , i.e., in the notation of §3,

$$(7.1) \quad f^{jk}(n, y) = \sum_{\mu=1}^g \sum_{\nu=1}^{h(\alpha)} \gamma_{jk\mu\nu}(n) y^{\mu\nu},$$

then the condition on $f(n, y)$ can be relaxed somewhat. Suppose that for some pair $(qk) = (q_0k_0)$, one has

$$(7.2) \quad c^{q_0k_0} = 1, \quad c^{qk} = 0 \quad \text{if } (qk) \neq (q_0k_0).$$

Take $j_0 = h(q_0) - k_0$, so that $\beta = h_0 - h(q_0) + k_0$. Let $l(q_0) = k(q_0) = k_0$. If β is not an integer, let $k(q)$ and $l(q)$ remain undefined for $q \neq q_0$, if β is an integer,

and $h(q) \geq \beta$, let $l(q) = k(q) = \beta$. For those q for which $h(q) < \beta$, $l(q)$ and $k(q)$ will be undefined in any case. Make the change of variable $y(n) = M(n)z(n)$, where $M(n)$ is as in §6, with β , $l(q)$ and $k(q)$ as above. The function $g(n, z)$ in the resulting system (6.18)–(6.19)–(6.20) will have the form

$$(7.3) \quad g^{jk}(n, z) = \sum_{\mu=1}^g \sum_{\nu=1}^{h(\mu)} \tilde{g}_{jk\mu\nu}(n) z^{\mu\nu}.$$

The proof given in §6 will work if

$$(7.4) \quad \sum |\tilde{g}_{jk\mu\nu}(n)| < \infty, \quad \text{for each } (jk\mu\nu),$$

and

$$(7.5) \quad \sum_n^{h_0-h(q_0)} |\tilde{g}_{q_0 k_0 \mu \nu}| < \infty, \quad \text{for each } (\mu\nu).$$

This will be the case if

$$(7.6) \quad \sum |\gamma_{jk\mu\nu}(n)| n^{\varepsilon(\alpha\beta) - \varepsilon(jk) + \varepsilon(\alpha)(h_0 - k(q))} < \infty$$

holds for each $(jk\mu\nu)$, where $\varepsilon(jk)$ is k or 1 according as $j = q$ or $j \neq q$, and $\varepsilon(j)$ is 1 or 0 according as $j = q_0$ or $j \neq q_0$. Thus when (7.1) and (7.6) hold, (3.1) has a solution $y = y(n)$ satisfying (6.9), where c_{qk} are as in (7.2).

For the d th order scalar difference equation

$$(7.7) \quad \Delta^d x(n) + a_1(n) \Delta^{d-1} x(n) + \cdots + a_d(n) x(n) = 0,$$

where $\Delta^k x(n) = \sum_{i=0}^k (-1)^{k-i} C_{ki} x(n+i)$, the above remark has the following implication. If

$$(7.8) \quad \sum n^{j-1} |a_j(n)| < \infty$$

for $j = 1, \dots, d$, then for each $k_0 = 0, 1, \dots, d-1$ (7.7) has a solution $x = x(n)$ satisfying

$$\Delta^k x(n) = C_{n \ k_0-k} + o(n^{k_0-k}) \quad \text{for } 0 \leq k \leq k_0,$$

and

$$\Delta^k x(n) = o(n^{k_0-k}) \quad \text{for } k_0 < k \leq d-1.$$

The equation (7.7) is equivalent to the case of (1.10), where the roots of the characteristic equation satisfy $\lambda_1 = \lambda_2 = \cdots = \lambda_d = 1$. Any case of (1.10) for which the characteristic equation has a single nonzero root of multiplicity d may be reduced to this case by a change of variable. If (7.7) is written in the form (1.10), then for the conclusion above to remain valid it is in general necessary to require

$$\sum_{j=1}^{\infty} n^{d-1} |b_j(n)| < \infty,$$

for $j = 1, \dots, d$.

8. A converse of Theorem 6.1. Theorem 6.1 admits the following partial converse:

THEOREM 8.1. *Let $\rho = \rho^m$ satisfy (6.2). Let h_* be defined by (6.1) and let h_0 satisfy (6.3). For each $n \geq 0$, let $f(n, y)$ be defined and continuous in y , for $|y| \leq \text{const.} (\neq 0)$. Let there exist a function $\phi(n, r)$ defined for all $n \geq 0$ and for small $r \geq 0$, continuous in r for each n , and satisfying (6.7). Let $\phi(n, r)$ have the form (6.10), where (6.11) holds, or let $\phi(n, r)$ satisfy, in addition to (6.5),*

$$(8.1) \quad \phi(n, r) \text{ is nondecreasing in } n \text{ for each fixed } r,$$

and in place of (6.6), for some δ , $0 < \delta < \rho$

$$(8.2) \quad \sum (\rho - \delta)^{-n} n^{h_0-1} \phi(n, \text{const.}(\rho - \delta)^n) < \infty, \quad \text{for every const.} > 0.$$

Let $y = y(n)$ be a solution of (3.1) satisfying (3.8) and (3.9). Then for some j_0 , $0 \leq j_0 < h_$, and some constants c^{qk} not all 0, y satisfies the asymptotic formula (6.9₁)–(6.9₂).*

An argument similar to one used in the proof below shows that (6.5), (8.1) and (8.2) imply (6.6).

Proof. The first step of the proof consists of showing that (3.8) and (3.9) imply

$$(8.3) \quad \sum n^{h_0-1} |f(n, y(n))| / |y(n)| < \infty.$$

If (6.7), (6.10) and (6.11) hold, and if $y(n)$ is any solution of (3.1) defined for all large n and such that $y(n) \neq 0$ for large n , then (8.3) is immediate. It will be shown that (8.3) is valid if $y(n)$ satisfies (3.8) and (3.9) when (6.7), (6.5), (8.1) and (8.2) hold.

Let $\delta > 0$ be such that (8.2) holds and let $\alpha(n)$ be the largest integer not exceeding $[\log(\rho - \delta)]^{-1} \log L_{ma}(n)$. It follows that

$$(8.4) \quad L_{ma}(n) \leq (\rho - \delta)^{\alpha(n)}$$

and

$$(8.5) \quad (L_{ma}(n))^{-1} \leq (\rho - \delta)^{-(\alpha(n)+1)}.$$

From (3.8) and (3.9) one has that for large n ,

$$(8.6) \quad \alpha(n) \leq n.$$

By (3.3) and (3.9) there exists a positive constant K such that

$$(8.7) \quad L_{ma}(n) \leq |y(n)| \leq K L_{ma}(n),$$

so by (6.5), (8.1), (8.4), (8.5) and (8.6),

$$(8.8) \quad |f(n, y(n))| / |y(n)| \leq (\rho - \delta)^{-(\alpha(n)+1)} \phi(\alpha(n), K(\rho - \delta)^{\alpha(n)}).$$

It follows from (3.8) and (8.7) that $\alpha(n) \rightarrow \infty$ as $n \rightarrow \infty$, hence by (8.2), the term on the right of (8.8) tends to zero as $n \rightarrow \infty$. In view of (3.12) and (8.7), this implies that there exists a $c > 0$ such that for all sufficiently large n , $\Delta \log L_m(n) < -c$. This in turn implies that there exists a positive integer $\mathfrak{R}$ such that the integral valued function $\alpha(n)$ takes any given value at most $\mathfrak{R}$ times, and that $\alpha(n) \sim \text{const.} \cdot n$ as $n \rightarrow \infty$. These facts and (8.2) imply the convergence of

$$\sum (\rho - \delta)^{-\alpha(n)} n^{h_0-1} \phi(\alpha(n), K(\rho - \delta)^{\alpha(n)}),$$

which together with (8.8) implies (8.3).

Let $f(n, y) = (f^1(n, y), \dots, f^d(n, y))$, and let $y = (y^1, \dots, y^d)$. For large n , define a matrix $\Gamma(n)$ as follows

$$(8.9) \quad \gamma_{jk}(n) = f^j(n, y(n)) \bar{y}^k(n) / |y(n)|^2,$$

where the bar denotes complex conjugation. By (8.3), $\Gamma(n)$ satisfies

$$(8.10) \quad \sum n^{h_0-1} |\Gamma(n)| < \infty,$$

so Theorem 6.1 is applicable to the linear system

$$(8.11) \quad y(n+1) = (J + \Gamma(n)) y(n).$$

The function $y(n)$, being a solution of (3.1), satisfies (8.11). The result follows by applying Theorem 6.1 to (8.11) and using the superposition principle.

9. Variants for the linear case of (3.1). When $f(n, y)$ has the form (7.1), one can obtain results concerning the asymptotic behavior of solutions of (3.1) under conditions different from those in Theorem 3.1. Theorems 9.1 and 9.2 below are, respectively, the analogues of (i) and (ii) of [5].

THEOREM 9.1. *In (3.1) let $f(n, y)$ be linear*

$$(9.1) \quad f^i(n, y) = \sum_{j=1}^d \gamma_{ij}(n) y^j, \quad i = 1, \dots, d,$$

where $y = (y^1, \dots, y^d)$ and $f = (f^1, \dots, f^d)$. Let $\lambda(1), \dots, \lambda(d)$ be the d eigenvalues of J , and let there exist an m , $1 \leq m \leq d$, with the property that $\lambda(m) \neq 0$, and $i \neq m$ implies $|\lambda(i)| \neq |\lambda(m)|$. Finally, for some σ on the range $1 \leq \sigma \leq 2$, let

$$(9.2) \quad \sum_{n=1}^{\infty} |\gamma_{ij}(n)|^\sigma < \infty,$$

for each $i, j = 1, \dots, d$. Then (3.1) possesses a solution $y(n) = (y^1(n), \dots, y^d(n))$, defined for all large n , such that as $n \rightarrow \infty$

$$(9.3) \quad y^m(n) \sim \prod_{i=1}^{n-1} (\lambda(m) + \gamma_{mm}(n)),$$

and

$$(9.4) \quad |y^i(n)| = o(|y^m(n)|) \quad \text{if } i \neq m.$$

Proof. The existence of $y(n) (\neq 0)$ satisfying (9.4) follows from Theorem 3.1. Lemma 2.3 and the proof of Theorem 3.1 imply in fact that $|y^i(n)|/|y^m(n)| \in l^\sigma$ for $i \neq m$. The latter relation and $1 \leq \sigma \leq 2$, $1/\sigma + 1/\sigma' = 1$ give

$$(9.5) \quad |y^i(n)|/|y^m(n)| \in l^{\sigma'} \quad \text{for } i \neq m.$$

One can write

$$(9.6) \quad y^m(n+1)/y^m(n) = (\lambda(m) + \gamma_{mm}(n))(1 + \phi(n)),$$

where

$$\phi(n) = \left(\sum_{i \neq m} \gamma_{mi}(n) y^i(n) / y^m(n) \right) / (\lambda(m) + \gamma_{mm}(n)).$$

By Hölder's inequality $\sum_{i \neq m} \gamma_{mi}(n) y^i(n) / y^m(n) \in l^1$, and hence so is $\phi(n)$. Thus the infinite product $\prod (1 + \phi(n))$ is convergent and (9.3) follows from (9.6).

THEOREM 9.2. Let h_* be defined by (6.1); q_0 a particular value of q , where $\rho = |\lambda(q)| > 0$; k_0 an integer satisfying $1 \leq k_0 \leq h(q_0)$. Let h_0 be a number satisfying (6.3) and let

$$(9.7) \quad \beta - k \neq 0 \quad \text{if } 1 \leq k \leq h(q) \text{ and } q \neq q_0,$$

where $\beta = h_0 - h_0(q_0) + k_0$. Let $f(n, y)$ satisfy (7.1), and for some σ , $1 \leq \sigma \leq 2$, let

$$(9.8) \quad \sum_{j,k,\mu,\nu} |\gamma_{jk\mu\nu}(n)| \sigma n^{\sigma\{\varepsilon(\mu\nu) - \varepsilon(jk) + \varepsilon(\alpha)(h_0 - h(q_0))\} + \sigma - 1} < \infty,$$

for each $(jk\mu\nu)$, where $\varepsilon(jk), \varepsilon(j)$ are as defined in §7. Then (3.1), (7.1) has a solution which satisfies, as $n \rightarrow \infty$

$$(9.9_1) \quad y^{qk}(n) = O(n^{k-\beta} \rho^n |\Lambda(n)|) \quad \text{if } q \neq q_0 \text{ or if } k < k_0,$$

$$(9.9_2) \quad y^{qk}(n) = C_{n,k-k_0} (\lambda(q))^{n-k+k_0} \Lambda(n) + o(n^{k-\beta} \rho^n |\Lambda(n)|) \quad \text{if } q = q_0 \text{ and } k \geq k_0,$$

and

$$(9.9_3) \quad y^{jk}(n) = o(n^{1-\beta} \rho^n |\Lambda(n)|) \quad \text{if } j \neq q,$$

where

$$(9.10) \quad \Lambda(n) = \prod_{m=n_0}^{n-1} \left(1 + \sum_{i=1}^{k_0} \sum_{v=k_0}^{h(q_0)} (-1)^{k_0-i} C_{k_0-i+m} C_{m,v-k_0} \cdot \lambda(q_0)^{2k_0-v-i-1} g_{q_0 i q_0 v}(m) \right).$$

Proof. Make the change of variables of §7. One obtains thus a system of the form (6.18)–(6.19)–(6.20), where $g(n, z)$ satisfies (7.3). From (9.8) it follows that for each $(jk\mu\nu)$

$$(9.11) \quad \sum_{\sigma=0}^{\infty} n^{\sigma-1} |g_{jk\mu\nu}|^{\sigma} < \infty,$$

and that for each $(\mu\nu)$

$$(9.12) \quad \sum_{\sigma=0}^{\infty} n^{\sigma(h_0-h(q_0))+\sigma-1} |g_{q_0k_0\mu}|^{\sigma} < \infty.$$

The proof of Theorem 6.1, with Lemma 2.4 replaced by Lemma 2.5, implies that the system (6.18)–(6.19)–(6.20) has a solution $z(n)$ such that $z^{q_0k_0}(n) \neq 0$ for large n ,

$$(9.13) \quad |z^{jk}(n)| = o |z^{q_0k_0}(n)| \quad \text{as } n \rightarrow \infty,$$

and

$$(9.14) \quad \sum_{\sigma=0}^{\infty} n^{-1} |z^{jk}(n)/z^{q_0k_0}(n)|^{\sigma} < \infty.$$

(Because of (9.7), $v(n)$, as defined by (6.30) satisfies $v(n) = |z^{q_0k_0}(n)|$, see the definition of $l(q), k(q)$ in §7.) The case q_0k_0 of (6.20) can be written

$$(9.15) \quad z^{q_0k_0}(n+1) = (\lambda(q) + \tilde{g}_{q_0k_0q_0k_0}(n) + \phi(n))z^{q_0k_0}(n),$$

where by (9.12), (9.14) and Hölder's inequality

$$(9.16) \quad \sum_{\sigma=0}^{\infty} n^{h_0-h(q_0)} |\phi(n)|^{\sigma} < \infty.$$

An argument like that used in the proof of Theorem 9.1 gives

$$z^{q_0k_0}(n) \sim (\lambda(q_0))^n \prod_{m=0}^{n-1} (1 + (\lambda(q_0))^{-1} \tilde{g}_{q_0k_0q_0k_0}(m));$$

in view of (9.16), this can be sharpened to

$$(9.17) \quad z^{q_0k_0}(n) = (\lambda(q_0))^n \prod_{m=0}^{n-1} (1 + (\lambda(q_0))^{-1} \tilde{g}_{q_0k_0q_0k_0}(m))(1 + o(n^{h(q_0)-h_0})).$$

Since

$$\tilde{g}_{q_0k_0q_0k_0}(n) = \sum_{i=1}^{k_0} \sum_{v=k_0}^{h(q_0)} (-1)^{k-i} C_{k_0-i+n, n} C_{n, v-k_0} (\lambda(q))^{2k_0-v-i} g_{q_0k_0q_0k_0}(n),$$

the formulae (9.9) follow from (9.13), (9.17) and the definition of the change of variable $y(n) = M(n)z(n)$ of §7.

10. Applications to the scalar difference equation. The following theorem of Evgrabov [2], is an immediate corollary of Theorem 6.1.

THEOREM 10.1. *Let the characteristic equation (1.11) of the difference equation (1.10) have d distinct, nonzero roots $\lambda_1, \dots, \lambda_d$. For $j = 1, \dots, d$ let $\sum^\infty |b_j(n)| < \infty$. Then for each $j = 1, \dots, d$, (1.10) has a solution $x_j = x_j(n)$ satisfying $x_j(n) = \lambda_j^n(1 + o(1))$ as $n \rightarrow \infty$.*

The remainder of this section will be concerned with the second order difference equation

$$(10.1) \quad x(n+2) + a_1(n)x(n+1) + a_2(n)x(n) = 0.$$

Rather than assuming that (10.1) is of the "almost constant coefficient" type it will be assumed that for some n_0 ,

$$(10.2) \quad a_1(n) \neq 0 \quad \text{for } n \geq n_0$$

and that,

$$(10.3) \quad \lim_{n \rightarrow \infty} 4a_2(n)/a_1(n)a_1(n-1) = p$$

exists. For $n > n_0$, let $\alpha(n)$ be defined by

$$(10.4) \quad 4a_2(n)/a_1(n)a_1(n-1) = p + \alpha(n).$$

THEOREM 10.2. *Let (10.2) hold for some n_0 and let there exist a constant p such that (10.3), (10.4) and $\sum |\alpha(n)| < \infty$ hold. Assume that p is neither 0 nor 1 and put $v = (1-p)^{1/2}$. Then (10.1) has solutions $x_\pm(n)$ satisfying respectively, as $n \rightarrow \infty$,*

$$x_\pm(n) \sim \left(-\frac{1}{2}\right)^n \left(\prod_{k=n_0}^{n-1} a_1(k)\right) (1 \pm v)^n.$$

The case $p = 1$ generalizes the almost constant coefficient case of (10.1), where the characteristic equation has a nonzero double root. For this case one has

THEOREM 10.3. *Let (10.2) and (10.3) hold. Assume that $p = 1$ and that $\alpha(n)$ defined by (10.4) satisfies $\sum |\alpha(n)| < \infty$. Then (10.1) has solutions $x_1(n)$ and $x_2(n)$ satisfying respectively, as $n \rightarrow \infty$*

$$x_1(n) \sim \left(-\frac{1}{2}\right)^n \prod_{k=n_0}^{n-1} a_1(k) \quad \text{and} \quad x_2(n) \sim \left(-\frac{1}{2}\right)^n n \prod_{k=n_0}^{n-1} a_1(k).$$

Proof of Theorems 10.2 and 10.3 Put

$$(10.5) \quad x(n) = \left(-\frac{1}{2}\right)^n \left(\prod_{k=n_0}^{n-1} a_1(k)\right) u(n) \quad \text{for } n > n_0.$$

Then (10.1) is transformed to

$$(10.6) \quad u(n+2) - 2u(n+1) + (p + \alpha(n))u(n) = 0.$$

The characteristic equation of (10.6), when $p \neq 1$ has the roots $(1 \pm v)$ and Theorem 10.2 follows from Theorem 10.1 and (10.5). When $p = 1$, (10.6) may be written $\Delta^2 u(n) + \alpha(n)u(n) = 0$, i.e., the case $d = 2$ of (7.7) and Theorem 10.3 follows from (10.5) and the remarks in §7. When (10.2) holds and $p = 0$, then (10.5) and Theorem 6.1 applied to (10.6), imply that (10.1) has a solution $x_1(n)$ which satisfies as $n \rightarrow \infty$

$$x_1(n) \sim (-1)^n \prod_{k=1}^{n-1} a_1(k).$$

By Theorem 3.1 (10.2) also has a solution $x_2 = x_2(n)$ such that as $n \rightarrow \infty$

$$x_2(n) = o(a^n |x_1(n)|)$$

for any a , $0 < a < 1$, Theorem 6.1 yields no additional information concerning this solution.

For the "almost constant coefficient" case of (10.1), (10.2) and $\sum |b_i(n)| < \infty$ for $i = 1, 2$, (or $\sum^\infty n |b_i(n)| < \infty$ for $i = 1, 2$), where $b_i(n) = a_i(n) - \lim_{n \rightarrow \infty} a_i(n)$, imply $\sum |\alpha(n)| < \infty$, (or $\sum^\infty n |\alpha(n)| < \infty$). Thus with the possible exception of the case where $\lim_{n \rightarrow \infty} a_1(n) = 0$, the applications of Theorem 6.1 to the almost constant coefficient case of (10.1) are contained in Theorems 10.2 and 10.3 and the remark above concerning the case $p = 0$. If $\lim_{n \rightarrow \infty} a_1(n) = 0$, then the characteristic equation has two nonzero roots λ , and $-\lambda$, or a double root 0. The former case is contained in Theorem 10.1, but Theorem 6.1 states nothing in general concerning the second case.

The application of Theorems 9.1 and 9.2 to equation (10.1) yields

THEOREM 10.4. *Let (10.2) and (10.3) hold. Assume that p is neither 0 nor a real number greater than 1. For some σ , $1 \leq \sigma \leq 2$, let $\alpha(n)$ in (10.4) satisfy*

$$(10.7) \quad \sum_{n=1}^{\infty} |\alpha(n)|^\sigma < \infty.$$

Then (10.1) has solutions $x_\pm(n)$ satisfying respectively, as $n \rightarrow \infty$,

$$x_\pm(n) = \left(-\frac{1}{2}\right)^n \prod_{k=1}^{n-1} (a_1(k)(1 \pm v \mp \alpha(k)/2v)).$$

If p is real and $p > 1$, the conclusion remains valid if (10.7) is replaced by the stronger condition

$$(10.8) \quad \sum_{n=1}^{\infty} |\alpha(n)|^\sigma n^{\tau-1} < \infty,$$

where $1 \leq \sigma \leq 2$ and $\tau > \sigma$.

The first case of this theorem (i.e., where p real implies $p \neq 0$ and $p < 1$) was proved by W. Ford [3] for $\alpha(n)$ having the form $\alpha(n) = \mu/n^{1/2+\delta} + \theta(n)$ where $0 < \delta \leq \frac{1}{2}$ and $\sum |\theta(n)| < \infty$. He also proves that if $\alpha(n)$ is of this form, p is real, and $p > 1$, so that $|1 - v| = |1 + v|$, then the result remains valid if

$|1 - v + \mu/2vn^{1/2+\delta}| = |1 + v - \mu/2vn^{1/2+\delta}|$ for all large n , i.e., if μ is real.

Proof of Theorem 10.4. After making the change of variables (10.5), write (10.6) as a system

$$(10.9) \quad \begin{pmatrix} v^1(n+1) \\ v^2(n+1) \end{pmatrix} = \begin{pmatrix} 0 & 1 \\ v^2 - 1 - \alpha(n) & 2 \end{pmatrix} \begin{pmatrix} v^1(n) \\ v^2(n) \end{pmatrix},$$

where $(v^1(n), v^2(n)) = (u(n), u(n+1))$. Put

$$\begin{pmatrix} w^1(n) \\ w^2(n) \end{pmatrix} = \frac{1}{2v} \begin{pmatrix} 1 & 1 \\ -(v-1) & v+1 \end{pmatrix} \begin{pmatrix} v^1(n) \\ v^2(n) \end{pmatrix},$$

so that (10.9) transforms to

$$(10.10) \quad \begin{pmatrix} w^1(n+1) \\ w^2(n+1) \end{pmatrix} = \begin{pmatrix} 1 - v + \alpha(n)/2v & \alpha(n)/2v \\ -\alpha(n)/2v & 1 + v - \alpha(n)/2v \end{pmatrix} \begin{pmatrix} w^1(n) \\ w^2(n) \end{pmatrix}.$$

The first part of the theorem follows by an application of Theorem 9.1 to (10.10).

If $p > 1$, and (10.8) holds, then the system (10.10) satisfies the hypothesis of Theorem 9.2 (h_0 may be taken to be $\tau/\sigma > 1$, so (9.7) holds). The result follows by an application of that theorem.

Finally, as an analogue of Theorem 10.3, one has

THEOREM 10.5. *Let (10.2) and (10.3) hold. Assume that $p = 1$ and that $\alpha(n)$ in (10.4) satisfies $\sum_{n=1}^{\infty} |\alpha(n)|^{\sigma} n^{2\sigma-1} < \infty$ for some σ and τ , where $1 \leq \sigma \leq 2$. Then (10.1) has solutions $x_1(n)$ and $x_2(n)$ satisfying respectively, as $n \rightarrow \infty$,*

$$x_1(n) \sim \left(-\frac{1}{2}\right)^n \left(\prod_{k=1}^{n-1} a_1(k)(1 + (k+1)\alpha(k))\right),$$

$$x_2(n) \sim \left(-\frac{1}{2}\right)^n n \left(\prod_{k=1}^{n-1} a_1(k)(1 - k\alpha(k))\right).$$

Proof. Make the change of variables (10.5), then the resulting equation (10.6) is equivalent to the system

$$\begin{pmatrix} v^1(n+1) \\ v^2(n+1) \end{pmatrix} = \begin{pmatrix} 1 & -\alpha(n) \\ 1 & 1 \end{pmatrix} \begin{pmatrix} v^1(n) \\ v^2(n) \end{pmatrix},$$

where $(v^1(n), v^2(n)) = (u(n+1) - u(n), u(n))$. Taking $h_0 = \tau/\sigma$ as before, the hypothesis of Theorem 9.2 is satisfied by the above system. An application of that theorem implies that (10.6) has solutions $u_1(n)$ and $u_2(n)$ satisfying respectively, as $n \rightarrow \infty$,

$$u_1(n) \sim \prod_{k=1}^{n-1} (1 + (k+1)\alpha(k)) \text{ and } u_2(n) \sim n \prod_{k=1}^{n-1} (1 - k\alpha(k)).$$

The conclusion of the theorem follows from (10.5).
