COMPLETELY MONOTONE SEQUENCES AS INVARIANT MEASURES⁽¹⁾

BY
RICHARD SCOVILLE

Introduction. A completely monotone sequence $\mathbf{a} = (a_0, a_1, a_2, \dots)$ of real numbers is a sequence which satisfies the conditions

$$(1) \quad (\Delta^n \mathbf{a})_k \geq 0 \quad (n = 0, 1, 2, \dots; \quad k = 0, 1, 2, \dots)$$

where the operator Δ , acting on any sequence $\mathbf{a}$, is the sequence $\Delta \mathbf{a}$ defined by

$$(\Delta \mathbf{a})_k = a_k - a_{k+1} \quad (k = 0, 1, 2, \dots).$$

During the first part of the paper we will suppose that the completely monotone sequence $\mathbf{a}$ also satisfies

$$(2) \quad \sum_{n=0}^{\infty} a_n = 1.$$

Using the sequence $\mathbf{a}$, we will construct a probability space $(X, \mathcal{B}, \mu)$ and a measure-preserving transformation T on it. This transformation will not, in general, be ergodic. We then make use of the Kryloff-Bogoliouboff decomposition [4] (as extended by Oxtoby [5]) of a measure into its ergodic parts. Writing μ as an integral of measures for which T is ergodic, and observing the effect of this decomposition on the sequence $\mathbf{a}$, we obtain the classical reduction of $\mathbf{a}$ to the form

$$a_k = \int_0^1 t^k dF(t) \quad (k = 0, 1, 2, \dots).$$

An inversion formula, similar to Feller's [2], giving F in terms of $\mathbf{a}$ can also be obtained in this way. In the last part of the paper we investigate the transformation T itself, and leave several interesting questions unanswered.

This paper is the major part of the author's dissertation prepared at Yale University under the direction of S. Kakutani, whom I wish to thank for his advice, encouragement and great skill.

$(X, \mathcal{B}, \mu)$ and the transformation T . Let us assume, then, that a sequence $\mathbf{a}$ satisfying (1) and (2) has been given and proceed with the construction of $(X, \mathcal{B}, \mu)$.

Let I_∞ be the one-point compactification of the non-negative integers, with ∞ the added point. We form the compact space

$$X'' = \prod_{i=1}^{\infty} X_i \quad (X_i = I_\infty, i = 1, 2, 3, \dots)$$

and consider the closed subset X' of X'' consisting of all sequences in X'' which are increasing (not necessarily strictly increasing), thinking of ∞ as being greater than every integer.

By a rectangle $(r_1, r_2, r_3, \dots, r_k)$ where $0 \leq r_1 \leq r_2 \leq \dots \leq r_k$, is meant all sequences in X' beginning with $r_1, r_2, r_3, \dots, r_k$, i.e., all sequences ω in X' for which $\omega_i = r_i$ ($i = 1, 2, 3, \dots, k$). The measure of a rectangle $R = (r_1, r_2, \dots, r_k)$ is defined as follows:

$$(3) \quad \mu(R) = \begin{cases} (\Delta^{k-1} a)_{r_k} & \text{if } r_k \neq \infty, \\ 0 & \text{if } r_k = \infty. \end{cases}$$

Let $\mathcal{A}$ be the (finitely additive) algebra consisting of all sets of X' which depend on only a finite number of coordinates, i.e., $\mathcal{A} = \bigcup \mathcal{A}_n$ where $\mathcal{A}_n$ consists of sets which can be written as the union of rectangles of length n . The measure of any set in $\mathcal{A}$ may now be defined by writing the set as a union of disjoint rectangles. This measure can be extended to a countably additive measure (again called μ) defined on $\mathcal{B}$, the smallest σ -field containing $\mathcal{A}$. Since μ is a regular measure on $\mathcal{A}$, this can be accomplished, for instance, by means of a theorem of Alexandroff [2, p. 138].

We let X be the subset of X' consisting of those sequences in which ∞ does not appear. The complement of X in X' may be written

$$X^c = \bigcup_{n=1}^{\infty} \bigcup_{i_1 \leq i_2 \leq \dots \leq i_n} (i_1, i_2, \dots, i_n, \infty).$$

This set clearly has measure zero, no matter what the sequence a may be, so we see that X has measure one. From now on when we speak of rectangles we mean rectangles restricted to the space X .

The transformation T is defined at a point $\omega = (\omega_1, \omega_2, \omega_3, \dots)$ of X as follows:

$$(4) \quad T\omega = \begin{cases} \underbrace{(0, 0, \dots, 0)}_{n-1}, \omega_n + 1, \omega_{n+1}, \dots & \text{if } \omega_1 = \omega_n < \omega_{n+1}, \\ (0, 0, 0, \dots) & \text{if } \omega_1 = \omega_2 = \omega_3 = \dots \end{cases}$$

Suppose $R = (r_1, r_2, \dots, r_n)$ is a rectangle in X . If $r_1 \neq 0$, the image of R under T^{-1} is again a rectangle: $(r_1 - 1, r_2, \dots, r_n)$. If $0 = r_1 = r_2 = \dots = r_k$ but $r_{k+1} \neq 0$ where $k < n$, the inverse image of R is the rectangle

$$\underbrace{(r_{k+1} - 1, r_{k+1} - 1, \dots, r_{k+1} - 1)}_{k+1}, r_{k+2}, \dots, r_n).$$

If, finally, $0 = r_1 = r_2 = \cdots = r_n$, the inverse image of R is, except for the constant sequences, the disjoint union

$$\bigcup_{p=1}^{\infty} \bigcup_{j=1}^{\infty} \bigcup_{i=0}^{j-1} \overbrace{(i, i, \dots, i, j)}^{n+p}.$$

Hence in any case the inverse image under T of any rectangle R is essentially a union of rectangles and so in particular is measurable. It is possible to calculate the measure of $T^{-1}R$ directly from formula (3) to show that T is measure-preserving, but the following "geometric" description of T is more enlightening but not essential to the development of the paper. This idea has been used before, for instance in [1].

We construct a sequence of line segments, $B_0, B_1, B_2, \dots$, one above the other as in Figure 1a so that the segment B_n has length a_n . Let us call the object so obtained a *building* and also regard it as a measure space by giving to each linear Borel set in the building its ordinary (linear) Lebesgue measure. Now if there were a measure-preserving transformation, say S , defined on B_0 , we could construct a measure-preserving transformation T on the building B by sending any point to the point directly above on the next floor, if possible, otherwise by descending straight down to B_0 and moving by S . Then S is simply the transformation induced by T on B_0 , of which we will speak later. What remains then is to define the transformation S on B_0 .

We can partially define S on B_0 by writing B_0 itself as a building as in Figure 1b so that the segment B'_n has length $a_n - a_{n+1}$. S is now partially defined on B_0 simply by rising one floor, if possible. To continue its definition, we must write B'_0 as a building in a way similar to the way we wrote B_0 as a building. Eventually then, S and hence T will be completely defined except perhaps on a set of measure zero. That we continue to get a building at each stage is due to the requirement (1) on the sequence a . The floors of the n th stage building will have lengths $(\Delta^{n-1}a)_0, (\Delta^{n-1}a)_1, \dots$.

Figure 1a

Figure 1b

The transformation T defined on X is said to be *conjugate* to the transformation S on Y if there is a 1-1 measure-preserving map ϕ from (almost all of) X onto (almost all of) Y such that ϕ^{-1} is measurable and $T = \phi^{-1} \circ S \circ \phi$. We can now show the relation between the two measure-preserving transformations defined so far.

LEMMA. *The transformation T defined on B is conjugate to the transformation T defined on X by (4).*

Proof. We can give coordinates to a point ω in B . Let ω_1 be the integer satisfying $\omega \in B_{\omega_1}$. Drop ω to the first floor of B and call this point ω' . Let ω_2 be the integer satisfying $\omega' \in B'_{\omega_2}$. Drop ω' to the first floor of B_0 and call this point ω'' . Let ω_3 satisfy $\omega'' \in B''_{\omega_3}$, etc. This correspondence $\omega \rightarrow (\omega_1, \omega_2, \dots)$ from B to X is easily seen to establish the conjugacy of T on B and T on X .

The measures μ for which T is ergodic. Since we will have to speak of several completely monotone sequences and their corresponding measures, we now write μ_a for the measure defined on X by means of the sequence a , and T_a for the corresponding transformation previously called simply T . Of course all the transformations T_a are identical, but we may wish to distinguish a particular measure μ_a which T preserves. In this case, we write T_a . For instance we could ask are T_a and T_b conjugate?

If a and b are completely monotone sequences which also satisfy (2), clearly any convex combination $\alpha a + \beta b$ is another. In fact, because of the linearity of Δ ,

$$(5) \quad \alpha \mu_a + \beta \mu_b = \mu_{\alpha a + \beta b}.$$

Also, given a completely monotone sequence $a \neq (1, 0, 0, 0, \dots)$, we can form two others, namely σa and τa defined by

$$(6) \quad \begin{aligned} (\sigma a)_n &= a_{n+1} / (1 - a_0), \\ (\tau a)_n &= (a_n - a_{n+1}) / a_0 \quad (n = 0, 1, 2, \dots). \end{aligned}$$

These sequences also satisfy (2) if a does.

Let $T_a|C$ be the transformation induced by T_a on the subset C of X of all sequences in X having first coordinate zero, and let $T_a|\tilde{C}$ be the induced transformation on $\tilde{C} = X - C$. Hence for instance $T_a|C$ is defined at a point ω of C by $T_a|C(\omega) = T^k \omega$ where k is the first positive integer for which $T^k(\omega) \in C$. $T_a|C$ is a measure preserving transformation on C . We call the measure ρ defined on subsets E of C by $\rho(E) = \mu_a(E) / \mu_a(C)$ the *induced measure* on C .

LEMMA. *Suppose $a \neq (1, 0, 0, \dots)$. Then the transformation $T_a|C$ on C with its induced measure, is conjugate to the transformation $T_{\sigma a}$ on X . Also, $T_a|\tilde{C}$ on $\tilde{C}$ with its induced measure is conjugate to $T_{\tau a}$.*

Proof. A glance at the buildings is probably enough to convince the reader of this fact, but we will construct mappings $\phi: C \rightarrow X$ and $\psi: \tilde{C} \rightarrow X$ which give the conjugacy explicitly. Let $\phi(\omega) = (\omega_2, \omega_3, \dots)$, $\omega \in C$ and $\psi(\omega) = (\omega_1 - 1, \omega_2 - 1, \dots)$, $\omega \in \tilde{C}$. Suppose $R = (r_1, r_2, \dots, r_k)$ is a rectangle in X . We must show that

$$\mu_{\tau a}(R) = \mu_a(\phi^{-1}R) / \mu_a(C)$$

and

$$\mu_{\sigma a}(R) = \mu_a(\psi^{-1}R) / \mu_a(\tilde{C}).$$

Since $\phi^{-1}(R) = (0, r_1, r_2, \dots, r_k)$, from (3) and (6) we get

$$\begin{aligned} \mu_{\tau a}(R) &= (\Delta^{k-1} \tau a)_{r_k} = (1/a_0) (\Delta^k a)_{r_k} \\ &= (1/\mu_a(C)) \mu_a(\phi^{-1}R). \end{aligned}$$

Similarly, $\psi^{-1}(R) = (r_1 + 1, r_2 + 1, \dots, r_k + 1)$ so that

$$\mu_{\sigma a}(R) = (\Delta^{k-1} \sigma a)_{r_k} = (1/(1 - a_0)) (\Delta^k a)_{r_k + 1} = (1/\mu_a(\tilde{C})) \mu_a(\psi^{-1}(R)).$$

These equations show that ϕ and ψ are indeed measure-preserving isomorphisms between C with its induced measure and X , and between $\tilde{C}$ with its induced measure and X , resp. If $\omega = (0, \omega_2, \omega_3, \dots)$ is any point in C , we see that $\phi \circ T_a|_C(\omega) = T(\omega_2, \omega_3, \dots) = T \circ \phi(\omega) = T_{\tau a} \circ \phi(\omega)$ and in the same way, we can show that $\psi \circ T_a|_{\tilde{C}} = T_{\sigma a} \circ \psi$, proving the lemma.

LEMMA. *If T_a is ergodic, then a is of the form*

$$(7) \quad a_n = \theta^n(1 - \theta) \quad (n = 0, 1, 2, \dots)$$

for some θ , $0 \leq \theta < 1$. (We set $\theta^0 \equiv 1$).

Proof. Suppose T_a is ergodic. If $a = (1, 0, 0, \dots)$ then certainly a has the form required in the lemma. We exclude this case from what follows. Hence the induced transformations $T_a|_C$ and $T_a|_{\tilde{C}}$ are defined, and they also are ergodic, since any transformation induced by an ergodic transformation is itself ergodic. Now by the previous lemma these induced transformations are conjugate to $T_{\tau a}$ and $T_{\sigma a}$ respectively so that $T_{\tau a}$ and $T_{\sigma a}$ are ergodic. Or what comes to the same thing T is ergodic with respect to the three measures $\mu_a, \mu_{\tau a}$ and $\mu_{\sigma a}$. But by (5) $\mu_a = (1 - a_0)\mu_{\sigma a} + a_0\mu_{\tau a}$. This implies, as is well known, that $\mu_a = \mu_{\tau a} = \mu_{\sigma a}$. In particular, $a_n = a_{n+1}/(1 - a_0)$, so that $a_n = (1 - a_0)^n a_0$ ($n = 0, 1, 2, \dots$). Setting $\theta = 1 - a_0$, we get the lemma. The measure μ_a , where a is given by (7), will sometimes be written μ_θ .

We conclude this section with one more lemma.

LEMMA. *If μ is a probability measure on X for which T is measure-preserving, then μ is of the form μ_a for some a satisfying (1) and (2).*

Proof. We must set $a_n = \mu(n)$, where (n) is the rectangle consisting of all sequences in X beginning with n . Given any rectangle $(r_1, r_2, \dots, r_k)$, we may write it as the image, under an appropriate power of T^{-1} , of the rectangle

$$\underbrace{(r_k, r_k, \dots, r_k)}_k.$$

Hence

$$\mu(r_1, r_2, \dots, r_k) = \mu(\underbrace{r_k, r_k, \dots, r_k}_k).$$

Now by induction on n we can prove that

$$(8) \quad (\Delta^n a)_k = \mu(\underbrace{k, k, \dots, k}_{n+1}) \quad (k = 0, 1, 2, \dots).$$

For $n = 0$, this is just the definition of a_k . Suppose (8) is true for $n = m - 1$. Then

$$\begin{aligned} (\Delta^m a)_k &= (\Delta^{m-1} a)_k - (\Delta^{m-1} a)_{k+1} \\ &= \mu(\underbrace{k, k, \dots, k}_m) - \mu(\underbrace{k+1, k+1, \dots, k+1}_m) \\ &= \sum_{i=k}^{\infty} \mu(\underbrace{k, k, \dots, k, i}_m) - \mu(\underbrace{k+1, k+1, \dots, k+1}_m) \\ &= \sum_{i=k+1}^{\infty} \mu(\underbrace{k, k, \dots, k, i}_m) - \mu(\underbrace{k+1, k+1, \dots, k+1}_m) + \underbrace{\mu(k, k, \dots, k)}_{m+1} \\ &= \sum_{i=k+1}^{\infty} \mu(\underbrace{k+1, k+1, \dots, k+1, i}_m) - \mu(\underbrace{k+1, k+1, \dots, k+1}_m) \\ &\quad + \underbrace{\mu(k, k, \dots, k)}_{m+1} = \mu(\underbrace{k, k, \dots, k}_{m+1}). \end{aligned}$$

This proves (8) for all n and hence proves the lemma.

The decomposition of μ . Let us first discuss the continuity properties of the transformation T .

LEMMA. *The transformation T on the set X is continuous. Moreover, T restricted to the subset U of X consisting of unbounded points*

$$U = \{\omega \in X : \lim_n \omega_n = \infty\}$$

is one-to-one and onto.

Proof. The second statement of the lemma is clear. To prove the first, suppose ρ is a point in X and that ρ^n is a sequence of points in X converging to ρ . If ρ is

not a constant sequence, $T\rho$ is determined by a finite number k of coordinates of ρ , say $\rho_1, \dots, \rho_k$. But for large n the first k coordinates of ρ^n must also be $\rho_1, \dots, \rho_k$, and hence $T(\rho^n)$ converges to $T\rho$. On the other hand, if ρ is a constant sequence, the first l coordinates of ρ^n are eventually all the same so that $T(\rho^n)$ converges to $(0, 0, \dots)$ which is of course $T\rho$.

Thus we can say that the system (T, U) is a *Borel system*. As Oxtoby has shown, the essential features of the Kryloff-Bogoliouboff decomposition remain valid in such a system. Let us emphasize the fact that the results of the Kryloff-Bogoliouboff paper do not apply to our situation directly, although perhaps through a modification of the space X (or of its topology) they could be made applicable.

The result that we make use of is this: to almost every point ω of X (i.e., to every point in a set which has measure one under *any* invariant measure) we can assign an ergodic measure μ_ω in such a way that, for any bounded Borel-measurable function f on X , the function

$$(9) \quad \int f d\mu_\omega$$

is measurable and, moreover, for any invariant measure μ_a on X , we have

$$(10) \quad \mu_a(R) = \int_X \mu_\omega(R) d\mu_a(\omega)$$

for any rectangle R in X .

Since μ_ω is ergodic, we have seen (7) that $\mu_\omega = \mu_\theta$ for some θ between 0 and 1. Let this number be $\theta(\omega)$. If, in equation (9), we put for f the characteristic function of the rectangle (0), we see that

$$\theta(\omega) = 1 - \int_X f d\mu_\omega$$

is a measurable function on X . If we let R be the rectangle (n) , equation (10) yields

$$(11) \quad a_n = \int_X \mu_{\theta(\omega)}(n) d\mu_a(\omega) = \int_X \theta(\omega)^n (1 - \theta(\omega)) d\mu_a(\omega).$$

Let $G_a(x)$ be the distribution function for $\theta(\omega)$ with respect to the measure μ_a , i.e.,

$$G_a(x) = \mu_a\{\theta(\omega) \leq x\}$$

so that (11) becomes

$$a_n = \int_0^1 t^n (1-t) dG_a(t) \quad (n = 0, 1, 2, \dots).$$

Setting $F_a(x) = \int_0^x (1-t) dG_a(t)$ we get the usual form of the representation:

$$a_n = \int_0^1 t^n dF_a(t) \quad (n = 0, 1, 2, \dots).$$

We are now in a position to prove the following theorem.

THEOREM. *If $\mathbf{b} = (b_0, b_1, b_2, \dots)$ is any completely monotone sequence, there is an increasing function $F_b(x)$ defined on the unit interval such that*

$$(12) \quad b_n = \int_0^1 t^n dF_b(t) \quad (n = 0, 1, 2, \dots).$$

Proof. Let $b_* = \lim b_n$. The sequence $\mathbf{a}$ defined by $a_n = (b_n - b_{n+1}) / (b_0 - b_*)$ ($n = 0, 1, 2, \dots$) is of course completely monotone, but also satisfies (2) (unless $b_0 = b_1 = \dots = b_*$, but this case can easily be handled separately). Hence, from the remarks above, we have $a_n = \int_0^1 t^n dF_a(t)$ ($n = 0, 1, 2, \dots$). Let $F_b(x) = (b_0 - b_*)L(x) + b_*\delta(x)$ where $L(x) = \int_0^x (1/(1-t))dF_a(t)$ and $\delta(x) = 1$ if $x = 1$ and zero otherwise. Then

$$\begin{aligned} \int_0^1 t^n dF_b(t) &= (b_0 - b_*) \int_0^1 (t^n / (1-t)) dF_a(t) + b_* \int_0^1 t^n d\delta(t) \\ &= (b_0 - b_*) \left(\int_0^1 (1/(1-t)) dF_a(t) - \sum_{k=0}^{n-1} \int_0^1 t^k dF_a(t) \right) + b_* \\ &= b_* + (b_0 - b_*) \left(\int_0^1 (1/(1-t)) dF_a(t) - \sum_{k=0}^{n-1} (b_k - b_{k+1}) / (b_0 - b_*) \right) \\ &= b_* + b_n - b_0 + (b_0 - b_*) \int_0^1 (1/(1-t)) dF_a(t) \\ &= b_* + b_n - b_0 + (b_0 - b_*) \int_0^1 dG_a(t) \\ &= b_n. \end{aligned}$$

Hence (12) holds and this proves the theorem.

An inversion formula. We will now try to express the function G_a explicitly in terms of the sequence $\mathbf{a}$.

LEMMA. *There is a subset V of X which has measure one under any T -invariant probability measure and is such that if ω is any point of V ,*

$$(13) \quad \lim_n (\omega_n / n) = \theta(\omega) / (1 - \theta(\omega)).$$

Proof. We will represent the space X in yet another way as the space Y of all sequences of non-negative integers. We map a point ω in X to the sequence $(\omega_1, \omega_2, -\omega_1, \omega_3 - \omega_2, \dots)$ in Y . If μ_θ is an ergodic measure on X , we find that the corresponding measure ν_θ on Y is given by

$$\nu_\theta(s_1, s_2, \dots, s_k) = \prod_{i=1}^k (1 - \theta) \theta^{s_i}$$

for any rectangle $S = (s_1, s_2, \dots, s_k)$ in Y . Hence ν_θ is a product measure in Y which is invariant under the shift transformation $(s_1, s_2, s_3, \dots) \rightarrow (s_2, s_3, s_4, \dots)$. We apply the ergodic theorem, for the shift transformation, to the function f defined on Y by $f(s_1, s_2, \dots) = s_1$. Then for almost every (ν_θ) point $(s_1, s_2, \dots)$ in Y we have

$$\begin{aligned} \lim_n (s_1 + s_2 + \dots + s_n)/n &= \int_Y f(s) d\nu_\theta(s) \\ &= \sum_{i=0}^{\infty} i(1-\theta)\theta^i = \theta/(1-\theta) \end{aligned}$$

or, in X ,

$$\lim_n (\omega_n/n) = \theta/(1-\theta) \quad \mu_\theta\text{-a.e.}$$

Clearly $\theta(\omega) = \theta$ on a set V_θ of μ_θ -measure one. Hence the set V on which the two measurable functions $\theta(\omega)/(1-\theta(\omega))$ and $\lim (\omega_n/n)$ coincide is a set which has measure one for any T -invariant measure. This proves the lemma.

THEOREM. *If $\mathbf{a}$ is any completely monotone sequence satisfying (2), G_a is given by*

$$(14) \quad G_a(x) = \lim_n \sum_{i=0}^{[nx/(1-x)]} \binom{n+i-1}{n-1} (\Delta^n \mathbf{a})_i$$

at every point x at which G_a is continuous.

Proof. First, from (13), we see that $\theta(\omega) = \lim_n \omega_n/(n + \omega_n)$, so that

$$\begin{aligned} \mu_a[\theta(\omega) < x] &\leq \lim_n \mu_a[\omega_n/(n + \omega_n) < x] \\ &\leq \mu_a[\theta(\omega) \leq x]. \end{aligned}$$

We calculate the center member of this inequality:

$$\begin{aligned} \mu_a[\omega_n/(n + \omega_n) < x] &= \mu_a[\omega_n < nx/(1-x)] \\ &= \sum_{i=0}^{[nx/(1-x)]} \mu_a[\omega_n = i] = \sum_{i=0}^{[nx/(1-x)]} \binom{n+i-1}{n-1} (\Delta^n \mathbf{a})_i \end{aligned}$$

where

$$\binom{n+i-1}{n-1}$$

is the number of rectangles of length n ending in i . Now, passing to the limit, we get

$$G_a(x-) \leq \sum_{i=0}^{[nx/(1-x)]} \binom{n+i-1}{n-1} (\Delta^n \mathbf{a})_i \leq G_a(x),$$

proving the theorem.

The transformations T_θ . We can obtain some information about the spectra of the measure-preserving transformations T_θ , although the results in this section are incomplete and probably not the best possible. Let us begin with the following theorem.

THEOREM. *If α is an eigenvalue of the transformation T_θ , then*

$$\lim_n \alpha^{B(n)} = 1 \quad \mu_\theta\text{-a.e.}$$

where $B(n)$ is the binomial coefficient

$$\binom{n + \omega_n}{n}.$$

Proof. Let f be the eigenfunction having eigenvalue α . For each ω in X , let ω^n be the rectangle $(\omega_1, \omega_2, \dots, \omega_n)$ of length n ; let $R(\omega, i, j)$ be the rectangle $(\omega_n, \omega_n, \dots, \omega_n, i, j)$ of length $n + 2$, and $S(\omega, i, j)$ be the rectangle $(\omega_1, \omega_2, \dots, \omega_n, i, j)$ of length $n + 2$. It is known that

$$\lim_n (1 / \mu_\theta(\omega^n)) \int_{\omega^n} f d\mu_\theta = f(\omega) \quad \text{a.e.}$$

and hence

$$\lim_n \left| (1 / \mu_\theta(\omega^n)) \int_{\omega^n} f d\mu_\theta \right| = 1 \quad \text{a.e.}$$

Estimating the value of $\left| \int_{\omega^n} f d\mu_\theta \right|$, we find

$$\begin{aligned} \left| \int_{\omega^n} f d\mu_\theta \right| &= \left| \sum_{j \geq i \geq \omega_n} \int_{S(\omega, i, j)} f d\mu_\theta \right| = \left| \sum_{j \geq i \geq \omega_n} \int_{R(\omega, i, j)} f d\mu_\theta \right| \\ &\leq \sum_{j=\omega_n}^{\infty} \left| \sum_{i=\omega_n}^{\infty} \int_{R(\omega, i, j)} f d\mu_\theta \right| \leq \sum_{j=\omega_n}^{\infty} \theta^j (1 - \theta)^{n+2} |G_n(j)| \end{aligned}$$

where $G_n(j)$ is a sum of powers of α , the powers being those powers of T which send the rectangle $R(\omega, \omega_n, j)$ into the rectangle $R(\omega, i, j)$ ($i = \omega_n, \omega_n + 1, \dots, j$).

Let $S(n, r)$ be the number of rectangles of length n which end in r . Let $P(n, s) = S(n, 0) + S(n, 1) + \dots + S(n, s)$. Note that the number $B(n)$, appearing in the statement of the theorem, is $P(n, \omega_n)$.

We leave to the reader the laborious task of showing that

$$(15) \quad |G_n(j)| = |1 + \alpha^{P(n, \omega_n)} + \dots + \alpha^{P(n, \omega_n) + \dots + P(n, j-1)}|.$$

Notice that this implies $|G_n(j)| \leq j - \omega_n + 1$. Now we have

$$\left| (1 / \mu(\omega^n)) \int_{\omega^n} f d\mu \right| \leq (1 / \theta^{\omega_n} (1 - \theta)^n) \sum_{j=\omega_n}^{\infty} \theta^j (1 - \theta)^{n+2} |G_n(j)| \leq 1.$$

Both sides of this inequality approach 1 as n approaches infinity, so, for the middle,

$$\lim_n (1 - \theta)^2 \sum_{j=0}^{\infty} \theta^j |G_n(\omega_n + j)| = 1 \quad \text{a.e.}$$

But this can happen only if $|G_n(\omega_n + j)|$ approaches $j + 1$ almost everywhere. Referring to (15), we see that $\alpha^{B(n)}$ approaches 1, almost everywhere. This is what we wished to prove.

THEOREM. *If $\theta < 1/2$, the transformation T_θ has no prime roots of unity as eigenvalues.*

Proof. Suppose α is a p th root of unity and is an eigenvalue. It is easy to see that the binomial coefficients

$$\binom{p^k + i}{p^k} \quad (k = 1, 2, \dots; i = 0, 1, \dots, p^k - 1)$$

are all equal to 1 (mod p). From the previous theorem we have

$$(16) \quad \lim_k \alpha^{\binom{p^k + \omega_{p^k}}{p^k}} = 1 \quad \text{a.e.}$$

On the other hand, from (13), we have

$$\lim_k \omega_{p^k} / p^k = \theta / (1 - \theta) < 1 \quad \text{a.e.}$$

since $\theta < 1/2$. That is, eventually $\omega_{p^k} < p^k$, so that eventually

$$(17) \quad \binom{p^k + \omega_{p^k}}{p^k} = 1 \pmod{p}.$$

Hence (16) and (17) together form the contradiction which proves the theorem.

We obtain the immediate

COROLLARY. *If $\theta < 1/2$, all powers of T_θ are ergodic.*

It is interesting to notice that the infinite product:

$$f(\omega) = \alpha^{\binom{1+\omega_1-1}{1}} \alpha^{\binom{2+\omega_2-1}{2}} \dots \alpha^{\binom{k+\omega_k-1}{k}} \dots$$

if it converges, is an eigenfunction with eigenvalue α . We have seen already that if α is an eigenvalue, then

$$(18) \quad \lim_n \alpha^{\binom{n+\omega_n}{n}} = 1 \quad \text{a.e.}$$

Integration of (18) over X yields

$$\lim_n (1 - \theta)^n \sum_{j=0}^{\infty} \theta^j \binom{n+j-1}{n-1} \alpha^{\binom{n+j}{n}} = 1.$$

Also left open is the question of the conjugacy of T_θ and T_θ^{-1} , and the question mentioned earlier, of the conjugacy of T_θ and T_ϕ , $\theta \neq \phi$.
