HIGHER DIMENSIONAL GENERALIZATIONS OF THE BLOCH CONSTANT AND THEIR LOWER BOUNDS

BY
KYONG T. HAHN⁽¹⁾

ABSTRACT. A higher dimensional generalization of the classical Bloch theorem depends in an essential way on the "boundedness" of the family of holomorphic mappings considered. In this paper the author considers two types of such "bounded" families and obtains explicit lower bounds of the generalized Bloch constants of these families on the hyperball in the space $\mathbb{C}^n$ in terms of universal constants which characterize the families.

1. Introduction. The classical Bloch theorem states that if $\mathcal{H}$ is the family of holomorphic mappings f from the unit disc into the complex plane $\mathbb{C}$ such that $|f'(0)| = 1$, and if $b(f)$ denotes the least upper bound of the radii of all univalent discs that f carries, then the Bloch constant

$$\beta(\mathcal{H}) = \inf\{b(f) : f \in \mathcal{H}\}$$

is positive. In this paper we study higher dimensional generalizations of this theorem and obtain explicit lower bounds for the generalized Bloch constants for various families of holomorphic mappings on the hyperball in terms of some universal constants which characterize the given family. The generalized Koebe constants are among such constants. In any effort to generalize the classical theorem of Bloch (or Koebe) to higher dimensional spaces one must first decide a suitable family of holomorphic (or biholomorphic) mappings to work with. Unlike in the case of one complex variable, the usual normalization ($f(0) = 0, |J_f(0)| = 1$) alone is not enough to guarantee the existence of a positive Bloch (or Koebe) constant. More precisely, the mappings: $w = f_n(z) = (nz_1, z_2/n)$ map the unit hyperball in $\mathbb{C}^2$ onto the circular domains of the form:

$$n^{-2}|w_1|^2 + n^2|w_2|^2 < 1,$$

which contains no hyperball of positive radius, see §2 for more details. In other words, the corresponding family $\mathcal{H}$ in the higher dimensional space $\mathbb{C}^n$, $n > 1$, is too vast to expect $\beta(\mathcal{H}) > 0$.

In this paper we consider two types of families, $\mathcal{H}$ and $\mathcal{H}_1$, see §2 for definitions, and obtain explicit lower bounds of the Bloch constants for $\mathcal{H}$ in §3 and for $\mathcal{H}_1$ in §4.

2. Generalized notions of Koebe and Bloch constants. Let D be a bounded homogeneous domain in the space $\mathbb{C}^n$ which is star-shaped with respect to $0 \in D$. D is *star-shaped* with respect to 0 if $z \in D$ implies $rz \in D$ for $0 \leq r \leq 1$. We denote $D_r = \{rz : z \in D\}$ and ∂D_r = the boundary of D_r . In particular, if D is the unit hyperball $B = \{z : |z| < 1\}$, $|z|^2 = |z_1|^2 + \dots + |z_n|^2$, then B_r is just the hyperball of radius $r > 0$.

Let $w = f(z)$ be a holomorphic mapping of D into the space $\mathbb{C}^n$. The mapping f is *univalent* in D if it is one-to-one in D . To each point $z^0 \in D$ we associate the number $d_f(z^0)$ as follows:

$$d_f(z^0) = \sup\{r > 0 : \text{there exists a subdomain } G \subset D \text{ such that}$$

$$f \text{ is univalent in } G \text{ and } f(z^0) + D_r \subset f(G)\},$$

if $J_f(z^0) \neq 0$, and $d_f(z^0) = 0$, otherwise; here $J_f(z^0)$ denotes the Jacobian of f at z^0 and $f(z^0) + D_r = \{f(z^0) + r\xi : \xi \in D\}$. Then $d_f(z)$ is a nonnegative continuous function of $z \in D$.

For each family $\mathcal{H}$ of holomorphic mappings $f : D \rightarrow \mathbb{C}^n$, we formally define the (generalized) *Bloch constant of D relative to $\mathcal{H}$* , or in brief, the *Bloch constant of $\mathcal{H}(D)$* , by

$$(1a) \quad \beta(\mathcal{H}) \equiv \beta(\mathcal{H}, D) = \inf\{b(f) : f \in \mathcal{H}\}$$

where

$$(1b) \quad b(f) = \sup\{d_f(z) : z \in D\}.$$

For each $t \in D$ we also define

$$(2) \quad \beta(\mathcal{H}, t) = \inf\{d_f(t) : f \in \mathcal{H}\}.$$

Then

$$(3) \quad \beta(\mathcal{H}, t) \leq \beta(\mathcal{H}) \quad \text{for all } t \in D.$$

If $\mathcal{H}_1$ and $\mathcal{H}_2$ are two families of holomorphic mappings $f : D \rightarrow \mathbb{C}^n$ with $\mathcal{H}_1 \subset \mathcal{H}_2$, then

$$(4) \quad \beta(\mathcal{H}_2) \leq \beta(\mathcal{H}_1).$$

Let $\mathcal{S}$ be the family of univalent holomorphic mappings $f : D \rightarrow \mathbb{C}^n$ with the following normalization conditions at 0:

$$(5a) \quad f(0) = 0,$$

$$(5b) \quad |J_f(0)| = 1.$$

The (generalized) Koebe constant of D relative to $\mathcal{S}$, or the Koebe constant of $\mathcal{S}(D)$, is defined to be the following number:

$$(6) \quad \kappa(\mathcal{S}) \equiv \kappa(\mathcal{S}, D) = \sup \left\{ r > 0 : D_r \subset \bigcap_{f \in \mathcal{S}} f(D) \right\}.$$

We note that

$$(7) \quad \kappa(\mathcal{S}) = \beta(\mathcal{S}, 0) \leq \beta(\mathcal{S}).$$

A standard normal family argument shows that $\kappa(\mathcal{S})$, and hence $\beta(\mathcal{S})$ are positive if the family $\mathcal{S}$ is bounded, see [2, Lemma 3]. On the other hand, a simple example shows that if $\mathcal{S}$ is unbounded, then $\kappa(\mathcal{S}) = 0$ and, also, $\beta(\mathcal{H}) = 0$ for any family $\mathcal{H}$ of holomorphic mappings which contains $\mathcal{S}$. The following example demonstrates this phenomenon:

Let $f_n : B \rightarrow \mathbb{C}^2$, where $B \subset \mathbb{C}^2$, be a sequence of biholomorphic mappings given by $f_n(z) = (nz_1, z_2/n)$ [5]. Clearly, $f_n(0) = 0$ and $J_{f_n}(0) = 1$. Furthermore, $|w_1|^2/n^2 + n^2|w_2|^2 < 1$ on B . Thus, the image domains $f_n(B)$ degenerate to the complex plane: $w_2 = 0$ as $n \rightarrow \infty$. Hence, $\bigcap_n f_n(B)$ contains no hyperball of a positive radius, which clearly implies $\kappa(\mathcal{S}) = 0$. It is also clear that $\beta(\mathcal{S}) = 0$. Hence, by (4), $\beta(\mathcal{H}) = 0$ if $\mathcal{S} \subset \mathcal{H}$. From this remark, the Bloch constant $\beta(\mathcal{H})$ being positive depends on the “boundedness” of the family $\mathcal{H}$.

By $\mathcal{S}(K)$ we denote the bounded family of univalent holomorphic mappings $f : D \rightarrow D_K$ satisfying (5a) and (5b). For this family $\mathcal{S}(K)$ we simply let $\kappa(K) = \kappa(\mathcal{S}(K))$. It is often convenient to work with the subfamily $\mathcal{S}_0(K) \subset \mathcal{S}(K)$ with (5b) replaced by

$$(8) \quad (df/dz)_0 = I_n,$$

where $(df/dz)_0$ denotes the Jacobian matrix of f at $z = 0$, and I_n the $n \times n$ identity matrix. For the Koebe constant of $\mathcal{S}_0(K)$, we use $\kappa_0(K) = \kappa(\mathcal{S}_0(K))$.

We note that $\kappa(\mathcal{S}, D) \leq 1$, as it follows easily from the generalized Koebe-Faber distortion theorem [2, Theorem 6]. (In [2] we used $r_0(D)$ for the Koebe constant of D relative to $\mathcal{S}$.)

Let λ_f^2 and Λ_f^2 denote the smallest and the largest characteristic values of the hermitian matrix A^*A , where $A \equiv A_f = (df/dz)$ is the Jacobian matrix of f and A^* the conjugate transpose of A . In this paper we consider the following two types of families:

$\mathcal{H}_1 \equiv \mathcal{H}_1(K) =$ the family of holomorphic mappings $f : \bar{D} \rightarrow \mathbb{C}^n$ such that there exists a constant $K > 0$ with

$$(I) \quad \max_{z \in \partial D_r} \Lambda_f(z) \leq K, \quad 0 \leq r \leq 1.$$

$\mathcal{H}_{II} \equiv \mathcal{H}_{II}(K)$ = the family of holomorphic mappings $f: \bar{D} \rightarrow \mathbb{C}^n$ such that there exists a constant $K > 0$ with

$$(II) \quad \max_{z \in \partial D_r} \Lambda_f(z) \leq K \max_{z \in \partial D_r} \lambda_f(z), \quad 0 \leq r \leq 1.$$

H. Wu ([1], [5]) calls the mapping $w = f(z)$ satisfying (II) for some $K > 0$ in the unit hyperball $\bar{B}$ a *quasi-conformal holomorphic mapping of order K* and shows essentially that every such mapping f , subject to the condition $|J_f(0)| \geq a > 0$, carries a univalent hyperball of positive radius. The Bloch constant of this family is then the largest among such positive numbers.

Remarks. (1) In the case of one complex variable, each holomorphic mapping f on the unit disc is a K -quasi-conformal mapping with $K = 1$.

(2) Under the condition (II), $|J_f(0)| \geq a > 0$ coincides essentially with the following condition:

$$(9) \quad \lambda_f(0) \geq a > 0.$$

Indeed, from $|J_f(0)| \geq \lambda_f^n(0)$ we know that $\lambda_f(0) \geq a$ implies $|J_f(0)| \geq a^n > 0$. Conversely, $a \leq |J_f(0)| \leq \Lambda_f^n(0)$ together with $\Lambda_f(0) \leq K\lambda_f(0)$ implies $\lambda_f(0) \geq a^{1/n}K^{-1} > 0$.

3. Lower bounds for the Bloch constants of $\mathcal{H}_I$. In this section, we determine lower bounds of the Bloch constants on the hyperball relative to the family $\mathcal{H}_I$ satisfying certain normalization conditions at $z = 0$.

We begin with the following lemma:

Lemma. Let $w = f(z)$ be a holomorphic mapping defined in a neighborhood of a point $t \in \mathbb{C}^n$ into $\mathbb{C}^n$ with $J_f(t) \neq 0$. Suppose that $\lambda_f \equiv \lambda_f(t)$ is the positive square root of the smallest characteristic value of the matrix A^*A at t , where $A \equiv (df/dz)$. Then the following hold:

(a) The mapping $w = f(z)$ is univalent in any open convex subset K , $t \in K$, of the set

$$(1) \quad \Omega_f = \{z : \|A(z) - A(t)\| < \lambda_f\},$$

where $\|A\| = \sup_{|x|=1} |Ax|$ and $|x|$ denotes the euclidean norm of the n -vector x .

(b) If r_0 is the radius of the largest hyperball contained in Ω_f centered at t , then $f[B(t, r_0)]$ contains the hyperball of radius $r_0\lambda_f/2$ centered at $f(t)$, where $B(t, r_0) = \{z : |z - t| < r_0\}$.

This lemma is a slight improvement over the result obtained by Takahashi [3]. We include here a proof for the sake of completeness.

Proof. Let z and z' be any two points in K and let σ be the line segment which joins z and z' in K . Then, by [4, p. 44],

$$(2) \quad f(z) - f(z') = \int_0^1 A(z' + s(z - z'))(z - z') ds.$$

Let $\zeta = z' + s(z - z')$, and rewrite (2) as follows:

$$(3) \quad f(z) - f(z') = A(t)(z - z') + \int_0^1 (A(\zeta) - A(t))(z - z') ds.$$

The triangle inequality together with the Schwarz inequality leads to

$$(4) \quad |f(z) - f(z')| \geq |A(t)(z - z')| - \int_0^1 \|A(\zeta) - A(t)\| |z - z'| ds.$$

Since σ is a compact subset of K , for all $\zeta \in \sigma$,

$$(5) \quad \|A(\zeta) - A(t)\| < \lambda_f(t)(1 - \epsilon)$$

for sufficiently small $\epsilon > 0$. Thus,

$$(6) \quad \begin{aligned} |f(z) - f(z')| &\geq \lambda_f(t)|z - z'| - \lambda_f(t)(1 - \epsilon)|z - z'| \\ &= \epsilon\lambda_f(t)|z - z'| > 0, \end{aligned}$$

from which $f(z)$ is univalent in K . Inequality (6) follows from (4) when we use (5) and

$$|A(t)(z - z')| \geq \lambda_f(t)|z - z'|.$$

This proves (a). To prove (b), we let $z' = t$ in (4). Then,

$$(7) \quad |f(z) - f(t)| \geq |A(t)(z - t)| - \int_0^1 \|A(\zeta) - A(t)\| |z - t| ds.$$

We write

$$F(s) = A(t + s(z - t)) - A(t) = A(\zeta) - A(t), \quad 0 \leq s \leq 1.$$

Then $F(0) = 0$, $F(1) = A(z) - A(t)$ and $\|F(s)\| = \|A(\zeta) - A(t)\| < \lambda_f$ for all $s \in [0, 1]$. Hence, by the classical Schwarz lemma,

$$(8) \quad \|F(s)\| = \|A(\zeta) - A(t)\| \leq \lambda_f(t)s.$$

From (7) and (8), we have

$$(9) \quad |f(z) - f(t)| \geq \lambda_f|z - t| - \lambda_f[s^2/2]_0^1|z - t| = \lambda_f|z - t|/2.$$

Thus, $f[B(t, r_0)] \supset B[f(t), \lambda_f r_0/2]$.

From this lemma we obtain the following theorem which gives some information about the set Ω_f :

Theorem 1. *Let $\mathcal{S}_0$ be the family of univalent mappings $w = f(z)$ on the unit hyperball B satisfying (8) of §2. If $f \in \mathcal{S}_0$, then the set*

$$(10) \quad \Omega_f = \{z : \|(df/dz)_z - I_n\| < 1\}$$

cannot cover B completely.

Proof. Suppose that $B \subset \Omega_f$. By the previous lemma, (b), $f(B)$ contains the hyperball of radius $1/2$. Hence,

$$(11) \quad \kappa_0 \equiv \kappa(\mathcal{S}_0) \geq 1/2.$$

But we always have that

$$(12) \quad \kappa_0 \leq 1/4.$$

Indeed, the mapping

$$(13a) \quad w = f(z) = (f_1(z), \dots, f_n(z))$$

with

$$(13b) \quad w_j = f_j(z) = z_j/(1 - z_j)^2, \quad j = 1, \dots, n,$$

carries B onto the product domain $S_1 \times \dots \times S_n$ univalently, where S_j is the complex plane minus the slit along the negative real axis from $-1/4$ to $-\infty$. (Observe that each $f_j(z)$ is the Koebe function.) Moreover, $f \in \mathcal{S}_0$. Hence, $\kappa_0 \leq 1/4$ which contradicts inequality (11). Therefore, Ω_f must leave out points of B .

Theorem 2. Let $w = f(z)$ be a holomorphic mapping of $\overline{B}_R$ in $\mathbb{C}^n$ into $\mathbb{C}^n$ such that

$$(14) \quad \Lambda_f(r) \equiv \max_{|z|=r} \Lambda_f(z) \leq K \quad \text{for all } r, 0 \leq r \leq R.$$

If $\lambda_f(0) \neq 0$, then the following hold:

- (a) $w = f(z)$ is univalent in the hyperball $B(0, r_0)$ with $r_0 = R\lambda_f(0)/2K$.
- (b) $f[B(0, r_0)]$ contains the hyperball $B[f(0), r_0\lambda_f(0)/2]$.

Proof. From (14), we have

$$(15) \quad \|A_f(z) - A_f(0)\| \leq \|A_f(z)\| + \|A_f(0)\| = \Lambda_f(z) + \Lambda_f(0) \leq 2K$$

for all $|z| \leq R$. By the Schwarz lemma, we obtain

$$(16) \quad \|A_f(z) - A_f(0)\| \leq 2K|z|/R \quad \text{for } |z| \leq R.$$

Indeed, let

$$(17) \quad g(t) = t^{-1}[A_f(tz/|z|) - A_f(0)]$$

for $t \in \mathbb{C}$ with $0 < |t| \leq R$, and $g(0) = 0$ for $t = 0$. By (15),

$$\|g(t)\| = \|A(tz/|z|) - A(0)\|/|t| \leq 2K/R \quad \text{for } |t| = R.$$

By the maximum principle,

$$\|g(t)\| \leq 2K/R \quad \text{for } |t| \leq R.$$

In particular, let $t = |z| \leq R$. Then,

$$\|g(|z|)\| = \|A(z) - A(0)\|/|z| \leq 2K/R,$$

which implies (16). From (16), we have

$$\|A(z) - A(0)\| < \lambda_f(0)$$

if $|z| < r_0$ with $r_0 = R\lambda_f(0)/2K$. By the above lemma, (a), $w = f(z)$ is univalent in $B(0, r_0)$. By the above lemma, (b), $w = f(z)$ maps $B(0, r_0)$ onto a domain which contains $B[f(0), r_0\lambda_f(0)/2]$. This proves the theorem.

Theorem 3. *The Bloch constant β_1 of the family $\mathcal{H}_1(K)$ of the holomorphic mappings $f: \bar{B}_R \rightarrow \mathbb{C}^n$, subject to the condition*

$$(18) \quad \lambda_f(0) \geq \alpha \quad \text{for some } \alpha > 0,$$

satisfies the following inequalities:

$$(19a) \quad \beta_1 \geq R\alpha^2/4K,$$

and

$$(19b) \quad \beta_1 \geq R\alpha^2\kappa_0(N)/2K, \quad N = K/\alpha,$$

in terms of the Koebe constant $\kappa_0(N)$.

Proof. Inequality (19a) is an immediate consequence of Theorem 2. To prove (19b), we define

$$(20) \quad g(\zeta) = [r_0 A_f(0)]^{-1} [f(r_0 \zeta) - f(0)].$$

Then $g(0) = 0$, $(dg/d\zeta)_0 = I_n$ and $w = g(\zeta)$ is univalent in B by Theorem 2. Thus, $g \in \mathcal{S}_0(B)$. Moreover, for $\zeta \in B$,

$$(21) \quad |g(\zeta)| \leq r_0^{-1} \|A_f^{-1}(0)\| |f(r_0 \zeta) - f(0)| \leq |f(r_0 \zeta) - f(0)|/r_0 \lambda_f(0).$$

Applying (2) of §3 to the mapping $w = f(z)$ with $z = r_0 \zeta$ and $z' = 0$, we have

$$f(r_0 \zeta) - f(0) = \int_0^1 A_f(sr_0 \zeta) r_0 \zeta \, ds, \quad 0 \leq s \leq 1.$$

Hence,

$$|f(r_0\zeta) - f(0)| \leq r_0 \int_0^1 \|A_f(sr_0\zeta)\| ds \leq r_0 K \quad \text{for } |\zeta| < 1.$$

From (21), we have

$$(22) \quad |g(\zeta)| \leq r_0 K / r_0 \lambda_f(0) \leq K/\alpha.$$

Thus, $g(B) \subset B_N$ with $N = K/\alpha$. By definition, the Koebe constant satisfies the following inequality:

$$\kappa_0 \equiv \kappa_0(N) \leq \min_{|\zeta|=1} |g(\zeta)|,$$

or

$$\kappa_0 r_0 \lambda_f(0) \leq \min_{|\zeta|=1} |f(r_0\zeta) - f(0)|.$$

This implies that the Bloch constant β_1 of the family $\mathcal{H}_1$ must satisfy

$$\beta_1 \geq \kappa_0 r_0 \lambda_f(0) \geq R\alpha^2 \kappa_0(N)/2K,$$

which establishes inequality (19b).

Corollary 1. *The Bloch constant of the family $\mathcal{H}_1(K)$ of holomorphic mappings $f: \overline{B} \rightarrow \mathbb{C}^n$ such that*

$$(23) \quad |J_f(0)| = 1$$

satisfies the following inequalities:

$$(24a) \quad \beta_1 \geq 1/4K^{2n-1}$$

and

$$(24b) \quad \beta_1 \geq \kappa_0(N)/2K^{2n-1}, \quad N = K^n.$$

Proof. If $f \in \mathcal{H}_1(K)$ satisfies (23), then

$$1 = |J_f(0)| \leq \lambda_f(0) \Lambda_f^{n-1}(0) \leq \lambda_f(0) K^{n-1}.$$

Hence, $1/K^{n-1} \leq \lambda_f(0)$. Inequalities (24a) and (24b) follow from (19a) and (19b), respectively, when we let $R = 1$ and $\alpha = K^{1-n}$.

Corollary 2. *The Bloch constant of the family $\mathcal{H}_1(K)$ of holomorphic mappings $f: \overline{B} \rightarrow \mathbb{C}^n$ such that*

$$(25) \quad (df/dz)_0 = I_n$$

satisfies the inequalities

$$(26a) \quad \beta_I \geq 1/4K$$

and

$$(26b) \quad \beta_I \geq \kappa_0(N)/2K, \quad N = K.$$

4. Lower bounds for the Bloch constants of $\mathcal{H}_{II}$.

Theorem 4. *The Bloch constant β_{II} of the family $\mathcal{H}_{II}(K)$ of K -quasi-conformal holomorphic mappings $f: \overline{B}_R \rightarrow \mathbb{C}^n$, subject to the condition (18) of §3, satisfies the following inequalities:*

$$(1a) \quad \beta_{II} \geq \alpha R/4(2K + 1)$$

and

$$(1b) \quad \beta_{II} \geq \alpha R \kappa_0(N)/2(2K + 1), \quad N = 2K,$$

in terms of the Koebe constant $\kappa_0(N)$.

Proof. Following the method used in [3], we define

$$(2a) \quad \varphi(r) = \lambda_f(r)(R - r),$$

where

$$(2b) \quad \lambda_f(r) = \max_{|z|=r} \lambda_f(z), \quad 0 \leq r \leq R.$$

Then $\varphi(0) = \lambda_f(0)R \geq \alpha R$ and $\varphi(R) = 0$. Since $\varphi(r)$ is a continuous function on $[0, R]$, there exists $r_0 \in [0, R]$ such that $\varphi(r_0) = \alpha R$ and $\varphi(r) < \alpha R$ for $r_0 < r \leq R$. Choose $z^0, |z^0| < R$ with $|z^0| = r_0$, such that

$$(3) \quad \varphi(r_0) = \lambda_f(r_0)(R - r_0) = \alpha R.$$

Then,

$$(4) \quad \lambda_f(r_0) = \alpha R/(R - r_0).$$

Let $\tau = (R - r_0)/2$. Then $B(z^0, \tau) \subset B(0, (R + r_0)/2) \subset B(0, R)$, since if $z \in B(z^0, \tau)$, then $|z| \leq |z^0| + |z - z^0| \leq r_0 + \tau = (R + r_0)/2 < R$. Set

$$(5) \quad g(\xi) = [\tau A_f(z^0)]^{-1}[f(z^0 + \tau\xi) - f(z^0)], \quad |\xi| \leq 1,$$

where $A_f(z) = (df/dz)_z$. We note that $A_f^{-1}(z^0)$ exists, since $|\det A_f(z^0)| \geq \lambda_f^n(z^0) > 0$. Observe that

$$(6) \quad (dg/d\xi) = A_f^{-1}(z^0)A_f(\xi), \quad \xi = z^0 + \tau\xi;$$

we have

$$(7) \quad \Lambda_g(\zeta) = \|A_g(\zeta)\| \leq \|A_f^{-1}(z^0)\| \|A_f(\xi)\| \leq \Lambda_f(\xi)/\lambda_f(z^0).$$

Hence,

$$(8) \quad \Lambda_g(\zeta) \leq K\lambda_f((R + r_0)/2)\lambda_f^{-1}(z^0) \leq 2K.$$

The first inequality in (8) follows from inequality (II) and the second inequality follows from (4) and (2a) with $\varphi(r) < \alpha R$. From (6), we also have: $\Lambda_g(0) = \lambda_g(0) = 1$. Thus,

$$(9) \quad \|A_g(\zeta) - A_g(0)\| \leq \Lambda_g(\zeta) + \Lambda_g(0) \leq 2K + 1 \quad \text{for } |\zeta| \leq 1.$$

By the Schwarz lemma, see (16) of §3,

$$(10) \quad \|A_g(\zeta) - A_g(0)\| \leq (2K + 1)|\zeta| \quad \text{for } |\zeta| \leq 1,$$

or,

$$(11) \quad \|A_g(\zeta) - I_n\| < 1 \quad \text{for } |\zeta| < 1/(2K + 1).$$

By the lemma, $w = g(\zeta)$ maps $B[0, 1/(2K + 1)]$ univalently onto a domain containing the hyperball $B[0, 1/(4K + 2)]$. From (5), $w = f(z)$ maps the subdomain $B[z^0, (R - r_0)/(4K + 2)]$ of $B(0, R)$ univalently onto a domain containing the hyperball $B[f(z^0), \alpha R/4(2K + 1)]$. This proves (1a). To obtain (2b), we let

$$(12) \quad h(\zeta) = [sA_g(0)]^{-1}[g(s\zeta) - g(0)], \quad s = 1/(2K + 1).$$

Then $h(0) = 0$, $(dh/d\zeta)_0 = I_n$ and $w = h(\zeta)$ is univalent in B , since g is univalent in $B(0, s)$. Thus, $h \in \mathcal{S}_0(B)$. Moreover,

$$(13) \quad |h(\zeta)| \leq |g(s\zeta) - g(0)|/s\lambda_g(0) = |g(s\zeta) - g(0)|/s,$$

from (6). Applying (2) of §3 for the mapping g with $z = s\zeta$ and $z' = 0$, we have

$$g(s\zeta) - g(0) = \int_0^1 A_g(ts\zeta)s\zeta dt.$$

The Schwarz inequality yields

$$|g(s\zeta) - g(0)| \leq \int_0^1 \|A_g(ts\zeta)\|s|\zeta| dt \leq s \int_0^1 \Lambda_g(ts\zeta) dt$$

for $|\zeta| \leq 1$. From (8),

$$|g(s\zeta) - g(0)| \leq 2Ks = 2K/(2K + 1),$$

and from (13),

$$(14) \quad |h(\xi)| \leq 2K/s(2K+1) = 2K.$$

By definition, the Koebe constant satisfies the following inequalities:

$$(15) \quad \begin{aligned} \kappa_0 \equiv \kappa_0(2K) &\leq \min_{|\xi|=1} |h(\xi)| = (2K+1) \min_{|\xi|=1} |g(s\xi)| \\ &\leq (2K+1) \min_{|\xi|=1} |f(z^0 + \tau\xi) - f(z^0)| / \tau\lambda_f(z^0). \end{aligned}$$

Hence,

$$(16) \quad \max_{|\xi-z^0|=\tau} |f(\xi) - f(z^0)| \geq \tau\lambda_f(z^0)\kappa_0/(2K+1) = \alpha R\kappa_0/2(2K+1),$$

from which we have (1b).

Corollary 1. *The Bloch constant of the family $\mathcal{H}_{II}(K)$ of K -quasi-conformal holomorphic mappings $f: \bar{B} \rightarrow \mathbb{C}^n$ such that $|J_f(0)| = 1$ satisfies the following inequalities:*

$$(17a) \quad \beta_{II} \geq K^{1/n}/4K(2K+1) \geq 1/4K(2K+1)$$

and

$$(17b) \quad \beta_{II} \geq K^{1/n}\kappa_0(2K)/2K(2K+1) \geq \kappa_0(2K)/2K(2K+1).$$

Proof. By inequality (II) with $z = 0$,

$$1 = |J_f(0)| \leq \lambda_f(0)\Lambda_f^{-1}(0) \leq K^{n-1}\lambda_f^n(0),$$

and, hence,

$$(18) \quad K^{(1-n)/n} \leq \lambda_f(0).$$

Inequalities (17a) and (17b) follow from (1a) and (1b) with $\alpha = K^{(1-n)/n}$ and $R = 1$ when we observe $K \geq 1$.

Corollary 2. *The Bloch constant of the family of K -quasi-conformal holomorphic mappings $f: \bar{B} \rightarrow \mathbb{C}^n$ such that $(df/dz)_0 = I_n$ satisfies the following inequalities:*

$$(19a) \quad \beta_{II} \geq 1/4(2K+1)$$

and

$$(19b) \quad \beta_{II} \geq \kappa_0(2K)/2(2K+1).$$

In particular, if $n = 1$, then $\beta_{II} > 1/12$.

Finally, from Theorem 4, we have the following corollary:

Corollary 3. *For any $f \in \mathcal{H}_{II}(K)$, defined on $\mathbb{C}^n$ and normalized by (18) of §3, there exists a domain $D \subset \mathbb{C}^n$ in which $w = f(z)$ is univalent and such that $f(D)$ contains the hyperballs of arbitrarily large radii.*
