ON SYMMETRIC ORDERS AND SEPARABLE ALGEBRAS

BY

T. V. FOSSUM⁽¹⁾

ABSTRACT. Let K be an algebraic number field, and let Λ be an R -order in a separable K -algebra A , where R is a Dedekind domain with quotient field K ; let Δ denote the center of Λ . A left Λ -lattice is a finitely generated left Λ -module which is torsion free as an R -module. For left Λ -modules M and N , $\text{Ext}_\Lambda^1(M, N)$ is a module over Δ . In this paper we examine ideals of Δ which are the annihilators of $\text{Ext}_\Lambda^1(M, -)$ for certain classes of left Λ -lattices M related to the central idempotents of A , and we compute these ideals explicitly if Λ is a symmetric R -algebra. For a group algebra, these ideals determine the defect of a block. We then compare these annihilator ideals with another set of ideals of Δ which are closely related to the homological different of Λ , and which in a sense measure deviation from separability. Finally we show that, for Λ to be separable over R , it is necessary and sufficient that Λ is a symmetric R -algebra, Δ is separable over R , and the center of each localization of Λ at the maximal ideals of R maps onto the center of its residue class algebra.

1. **Annihilators of Ext .** We will adhere to the notation and assumptions in the introduction throughout this paper: That is, Λ is an R -order in a separable K -algebra A . If M and N are left Λ -modules, then $\text{Ext}_\Lambda^1(M, N)$ is an $(\text{End}_\Lambda(M), \text{End}_\Lambda(N))$ -bimodule. The ring homomorphism from Δ into $\text{End}_\Lambda(M)$ given by left multiplication makes $\text{Ext}_\Lambda^1(M, N)$ into a left Δ -module.

When M is a left Λ -lattice, we may identify M with a subset of $K \otimes_R M$ by the map $m \rightarrow 1 \otimes m$, and under this identification we have that $KM = K \otimes_R M$. It is clear that KM is a left A -module, and in this context we may speak of aM for any $a \in A$. It is equally obvious that to each Λ -homomorphism $f: M \rightarrow N$ of left Λ -lattices, there is a unique extension $f: KM \rightarrow KN$ (which we still denote by f) which is an A -homomorphism. We will use these conventions frequently and without further mention.

Definition. For M a left Λ -lattice, set

$$\text{Ann}_\Delta(\text{Ext}_\Lambda^1(M, -)) = \bigcap_N \{\text{Ann}_\Delta(\text{Ext}_\Lambda^1(M, N))\},$$

where the intersection is over all left Λ -modules N , and where $\text{Ann}_\Delta(E) = \{z \in \Delta: zE = 0\}$ for any left Δ -module E . For a central idempotent e of A , define $J_\Delta(\Lambda, e) = \bigcap_{eM=M} \{\text{Ann}_\Delta(\text{Ext}_\Lambda^1(M, -))\}$, where the intersection

is over all left Λ -lattices M such that $eM = M$. Set $J_\Delta(\Lambda) = J_\Delta(\Lambda, 1)$, and $J_R(\Lambda, e) = J_\Delta(\Lambda, e) \cap R$.

Ideals related to $J_\Delta(\Lambda, e)$ have been studied by Jacobinski [5], Roggenkamp [6] and others.

Clearly $J_\Delta(\Lambda) = \Delta$ if and only if each left Λ -lattice is projective, that is, if and only if Λ is left hereditary. Let $\Lambda^e = \Lambda \otimes_R \Lambda^0$ be the enveloping algebra of Λ , so that the multiplication map $\epsilon: \Lambda^e \rightarrow \Lambda$, given by $\epsilon(a \otimes b) = ab$, is a left Λ^e -homomorphism; then ϵ induces the map $\epsilon_*: \text{Hom}_{\Lambda^e}(\Lambda, \Lambda^e) \rightarrow \Delta$ by $\epsilon_*(f) = \epsilon f(1)$. The image $H_\Delta(\Lambda)$ of ϵ_* is an ideal of Δ , called the homological different of Λ (see Auslander and Goldman [1]). Since A is a separable K -algebra, it can be shown that $H_\Delta(\Lambda)$ is a nonzero ideal of Δ contained in $J_\Delta(\Lambda)$, and which spans the center $Z(A)$ of A over K (see for example [7, Chapter V]). It follows that $\text{Ext}_\Lambda^1(M, N)$ is a torsion R -module for all left Λ -lattices M and all left Λ -modules N .

Let M be a left Λ -module. An endomorphism $\sigma \in \text{End}_\Lambda(M)$ is called *projective* if, for every exact sequence $X \rightarrow M \rightarrow 0$ of left Λ -modules, there exists $\theta \in \text{Hom}_\Lambda(M, X)$ such that the diagram

$$\begin{array}{ccc} & M & \\ \theta \swarrow & \downarrow \sigma & \\ X & \longrightarrow M & \longrightarrow 0 \end{array}$$

commutes.

Lemma 1.1. *Let M be a left Λ -module. Then $\sigma \in \text{End}_\Lambda(M)$ is projective if and only if $\sigma \text{Ext}_\Lambda^1(M, -) = 0$.*

Proof. See Roggenkamp [6, Lemma 1].

If M is a left Λ -module and if $z \in \Delta$, then it follows from this lemma that $z \text{Ext}_\Lambda^1(M, -) = 0$ if and only if the left multiplication endomorphism λ_z of M is projective.

Our first result shows that $J_\Delta(\Lambda, e)$ can be computed directly in terms of $J_\Delta(\Lambda)$.

Theorem 1.2. *Let e be a central idempotent of Λ . Then $J_\Delta(\Lambda, e) = \{z \in \Delta: ze \in J_\Delta(\Lambda)\}$.*

Proof. To show the inclusion $\supseteq$, assume $z \in \Delta$ and $ze \in J_\Delta(\Lambda)$. Let M be a left Λ -lattice such that $eM = M$, so that the left multiplications λ_z and λ_{ze} on M are identical. Now $ze \in J_\Delta(\Lambda)$ implies that $\lambda_z = \lambda_{ze}$ is projective, hence $z \in J_\Delta(\Lambda, e)$.

For the inclusion $\subseteq$, fix $z \in J_\Delta(\Lambda, e)$. We will show first that $ze \in \Delta$.

Lemma 1.3. *Let e be a central idempotent of A . If $\sigma \in \text{End}_\Lambda(e\Lambda)$ is projective, then $\sigma(e) \in \Lambda$.*

Proof. Let the epimorphism $\Lambda \rightarrow e\Lambda$ be given by $a \rightarrow ea$. Since σ is projective, there exists $\theta \in \text{Hom}_\Lambda(e\Lambda, \Lambda)$ such that the diagram

$$\begin{array}{ccc} & e\Lambda & \\ \theta \swarrow & \downarrow \sigma & \\ \Lambda & \xrightarrow{\quad} & e\Lambda \longrightarrow 0 \end{array}$$

commutes. In particular, $e\theta(e) = \sigma(e)$. Choose $0 \neq r \in R$ such that $re \in \Lambda$. Then $r\sigma(e) = re\theta(e) = \theta(re) = r\theta(e)$, and since Λ is R -torsion free, $\sigma(e) = \theta(e) \in \Lambda$, as desired.

As a trivial consequence, we deduce the following well-known result about hereditary orders.

Corollary 1.4. *If Λ is hereditary, then Λ contains each central idempotent of A ; in particular, Λ is the ring direct product of R -orders in simple K -algebras.*

We continue with the proof of Theorem 1.2. Since $z \in J_\Delta(\Lambda, e)$, the left multiplication λ_z on $e\Lambda$ is projective. By the lemma, $ze = \lambda_z(e) \in \Lambda$, so in fact $ze \in \Delta$.

Now let N be a left Λ -lattice, and let $X \xrightarrow{g} N \rightarrow 0$ be an exact sequence of Λ -modules. We need to show that the left multiplication λ_{ze} is a projective endomorphism of N . The obvious map $N \rightarrow eN$ is an epimorphism, so we have the solid part of the diagram

$$(*) \quad \begin{array}{ccc} & eN & \\ \theta \swarrow & \downarrow \lambda_z & \\ X & \xrightarrow{eg} & eN \longrightarrow 0, \end{array}$$

where eg is the composite $X \xrightarrow{g} N \rightarrow eN$. Clearly $\lambda_z = \lambda_{ze}$ on eN , and $e(eN) = eN$. Since $z \in J_\Delta(\Lambda, e)$, we see that λ_z is a projective endomorphism of eN , so there exists $\theta \in \text{Hom}(eN, X)$ such that the diagram $(*)$ commutes. Now let $\phi = \theta e$ be the composite $N \rightarrow eN \xrightarrow{\theta} X$, so that $\phi(n) = \theta(en)$ for all $n \in N$. It is easy to check that the diagram

$$\begin{array}{ccc} & N & \\ \phi \swarrow & \downarrow \lambda_{ze} & \\ X & \xrightarrow{g} & N \longrightarrow 0 \end{array}$$

commutes, using the technique in the proof of Lemma 1.3. It follows that $ze \in J_\Delta(\Lambda)$, which completes the proof.

Corollary 1.5. *Let e be a central idempotent of A . Then $eJ_{\Delta}(\Lambda) = eJ_{\Delta}(\Lambda, e) \subseteq J_{\Delta}(\Lambda)$.*

Proof. By Theorem 1.2, $eJ_{\Delta}(\Lambda, e) \subseteq J_{\Delta}(\Lambda)$, so $eJ_{\Delta}(\Lambda, e) \subseteq eJ_{\Delta}(\Lambda)$. Clearly $J_{\Delta}(\Lambda) \subseteq J_{\Delta}(\Lambda, e)$. Therefore $eJ_{\Delta}(\Lambda) = eJ_{\Delta}(\Lambda, e) \subseteq J_{\Delta}(\Lambda)$, as desired.

Let e_1, e_2 be orthogonal central idempotents of A , and set $e = e_1 + e_2$. Then e is a central idempotent of A , and it is clear from the definition that $J_{\Delta}(\Lambda, e_i) \supseteq J_{\Delta}(\Lambda, e)$ for $i = 1, 2$. If $z \in J_{\Delta}(\Lambda, e_1) \cap J_{\Delta}(\Lambda, e_2)$, then by Theorem 1.2, $ze_1, ze_2 \in J_{\Delta}(\Lambda)$, and so $ze = ze_1 + ze_2 \in J_{\Delta}(\Lambda)$; therefore $z \in J_{\Delta}(\Lambda, e)$. We have thus proved the following intersection property.

Theorem 1.6. *Let e_1, e_2 be orthogonal central idempotents of A . Then*

$$J_{\Delta}(\Lambda, e_1) \cap J_{\Delta}(\Lambda, e_2) = J_{\Delta}(\Lambda, e_1 + e_2).$$

A *block* idempotent of a ring B is a nonzero central idempotent which cannot be expressed as the sum of two nonzero orthogonal central idempotents of B . Since the K -algebra A is semisimple, its block idempotents are in one-to-one correspondence with its simple ring direct factors, and every central idempotent of A is the sum of block idempotents. It follows from the above theorem by induction that if $e_1, \dots, e_r$ are the block idempotents of A , then $J_{\Delta}(\Lambda, e) = \bigcap_{e_i e = e_i} \{J_{\Delta}(\Lambda, e_i)\}$ for any central idempotent e of A .

2. $J_{\Delta}(\Lambda)$ for symmetric algebras. We adhere to the notation and assumptions of §1. In addition, we shall use the following notation through the remainder of the paper:

Let $e_1, \dots, e_r$ be the block idempotents of A . Set
 $A_j = e_j A$,
 $K_j = Z(A_j)$, the center of A_j ,
 $n_j = (A_j : K_j)^{1/2}$,
 R_j = the integral closure of R in K_j ,
 U_j = the reduced trace of A_j over K_j ,
 T_j = the trace of K_j over K ,
 $S_j = T_j \circ U_j$,
 for all j such that $1 \leq j \leq r$.

Let B be a finitely generated S -algebra, where S is a commutative ring. We say the pair (B, ϕ) is a *symmetric S -algebra* if $\phi: B \rightarrow \text{Hom}_S(B, S)$ is an isomorphism as left B^e -modules, where $B^e = B \otimes_S B^0$. We say B is a *symmetric algebra* if there exists a ϕ such that (B, ϕ) is a symmetric algebra. It is well known that every finitely generated semisimple algebra over a field E is a symmetric E -algebra. Furthermore, if G is a finite group, then the group algebra SG is a

symmetric S -algebra for any commutative ring S .

Let Γ be an R -order (in A) containing Λ , and set $(\Lambda: \Gamma)_{\Lambda} = \{a \in \Lambda: \Gamma a \subset \Lambda\}$. Then $(\Lambda: \Gamma)_{\Lambda}$ is an ideal in Λ , and it is also a left ideal in Γ . Set $(\Lambda: \Gamma)_{\Delta} = (\Lambda: \Gamma)_{\Lambda} \cap \Delta$.

Proposition 2.1 (Roggenkamp [6]). *If Γ is a hereditary R -order containing Λ , then $(\Lambda: \Gamma)_{\Delta} \subseteq J_{\Delta}(\Lambda) \subseteq (\Lambda: \Gamma)_{\Lambda} \Gamma \cap \Delta$. In particular if $(\Lambda: \Gamma)_{\Lambda} \Gamma = (\Lambda: \Gamma)_{\Lambda}$, then $J_{\Delta}(\Lambda) = (\Lambda: \Gamma)_{\Delta}$.*

We proceed to compute $(\Lambda: \Gamma)_{\Lambda}$ in case Λ is a symmetric R -algebra and Γ is a maximal R -order containing Λ , following Jacobinski [5].

Let (Λ, ϕ) be a symmetric R -algebra. We can extend ϕ to a left A^e -isomorphism $\phi: A \rightarrow \text{Hom}_K(A, K)$. Since K has characteristic zero, the reduced trace S_j of A_j over K is nonzero, and it follows from [4, Theorem 1.3] that $\phi^{-1}(S_j)$ is a nonzero element in K_j for each j , $1 \leq j \leq r$. Let ρ be the character of the left regular module ${}_A A$. One checks that $\rho = \sum_j n_j S_j$, and it follows that $\sum_j n_j \phi^{-1}(S_j) = \phi^{-1}(\rho)$ is a unit in the center of A . (In [4] we showed that if $(a_i), (b_i)$ are dual bases for A with respect to ϕ , then $\sum_i a_i b_i = \phi^{-1}(\rho)$.) Since Λ is integral over R , the restriction of ρ to Λ maps Λ into R , and so $\phi^{-1}(\rho)$ belongs to the center of Λ .

Definition. Let (Λ, ϕ) be a symmetric R -algebra, and let ρ be the character of the left regular module ${}_A A$. The *order* of (Λ, ϕ) is defined to be $\phi^{-1}(\rho)$.

Remarks. (1) If $G = \{g_1, g_2, \dots, g_n\}$ is a finite group, then RG is a symmetric algebra with respect to an isomorphism ϕ such that $(g_i), (g_i^{-1})$ are dual bases with respect to ϕ . In this case the order of (RG, ϕ) is $\sum_i g_i g_i^{-1} = n$, the order of G . It is this fact that motivates the general definition.

(2) If Λ is a symmetric algebra with two Λ^e -isomorphisms $\phi_1, \phi_2: \Lambda \rightarrow \Lambda^*$, one can show that $\phi_1^{-1}(\rho)$ is a multiple of $\phi_2^{-1}(\rho)$ by a unit in the center Δ of Λ . Therefore the ideals of Δ generated by the orders of (Λ, ϕ_1) and (Λ, ϕ_2) are equal.

If L is a finitely generated R -submodule of A such that $KL = A$, set $L^{\phi} = \{a \in A: \phi(1)(aL) \subseteq R\}$. Then $L \rightarrow L^{\phi}$ reverses strict inclusions, and $(L^{\phi})^{\phi} = L$. Since $\phi: \Lambda \rightarrow \Lambda^* = \text{Hom}_R(\Lambda, R)$ is an isomorphism, one checks that $\Lambda^{\phi} = \Lambda$. Now if Γ is any order containing Λ , then $\Lambda^{\phi} \Gamma = \Gamma$ is the smallest right Γ -lattice containing Λ^{ϕ} , so Γ^{ϕ} is the largest left Γ -lattice contained in Λ ; that is, $\Gamma^{\phi} = (\Lambda: \Gamma)_{\Lambda}$. Since $\phi(1)(xa) = \phi(1)(ax)$ for all $x, a \in A$ (see [4, Theorem 1.3]), it follows that Γ^{ϕ} is a two-sided ideal of Γ contained in Λ .

Now assume that Γ is a maximal R -order containing Λ , and as before let c denote the order of (Λ, ϕ) . Since Γ is maximal, we have a decomposition $\Gamma = \Gamma_1 + \dots + \Gamma_r$, where each Γ_j is a maximal order in A_j . Note also that R_j is the center of Γ_j for each j . Now $\rho = \sum_j n_j S_j$, so it follows easily that

$\{a \in A: \rho(a\Gamma) \subseteq R\} = \sum_j (1/n_j) d_{S_j}^{-1}(\Gamma_j)$, where we use the notation of [7, Chapter V, § 1] by writing $d_{S_j}^{-1}(\Gamma_j) = \{a \in A_j: S_j(a\Gamma_j) \subseteq R\}$. Similarly define $d_{U_j}^{-1}(\Gamma_j)$ and $d_{T_j}^{-1}(R_j)$.

Now $\phi(1) = c^{-1}\phi(c) = c^{-1}\rho$, so $(\Lambda: \Gamma)_{\Lambda} = \Gamma^{\phi} = \{a \in A: \phi(1)(a\Gamma) \subseteq R\} = \{a \in A: (c^{-1}\rho)(a\Gamma) \subseteq R\} = c\{a \in A: \rho(a\Gamma) \subseteq R\} = \sum_j (c/n_j) d_{S_j}^{-1}(\Gamma_j)$, by the above paragraph. From the equalities $d_{S_j}^{-1}(\Gamma_j) = d_{U_j}^{-1}(\Gamma_j) d_{T_j}^{-1}(R_j)$, we have the following:

Lemma 2.2. *Let Γ be a maximal order containing Λ . If (Λ, ϕ) is a symmetric R -algebra of order c , then*

$$(\Lambda: \Gamma)_{\Lambda} = \sum_j (c/n_j) d_{U_j}^{-1}(\Gamma_j) d_{T_j}^{-1}(R_j),$$

and

$$(\Lambda: \Gamma)_{\Lambda} \Gamma = (\Lambda: \Gamma)_{\Lambda}.$$

Since K is an algebraic number field, $d_{U_j}^{-1}(\Gamma_j) \cap K_j = R_j$ for each j (see [7, p. 270]). From this, together with our observation that $\Gamma^{\phi} = (\Lambda: \Gamma)_{\Lambda}$ is a two-sided ideal of Γ , we apply Proposition 2.1 to obtain a characterization of $J_{\Delta}(\Lambda)$ for symmetric algebras (compare Jacobinski [5] and Roggenkamp [6]).

Theorem 2.3. *Let (Λ, ϕ) be a symmetric R -algebra of order c . Then $J_{\Delta}(\Lambda) = \sum_j (c/n_j) d_{T_j}^{-1}(R_j)$. Furthermore, if e is a central idempotent of A , then*

$$eJ_{\Delta}(\Lambda) = \sum_{e_j e = e_j} (c/n_j) d_{T_j}^{-1}(R_j),$$

and

$$J_R(\Lambda, e) = \bigcap_{e_j e = e_j} \{(c/n_j) d_{T_j}^{-1}(R_j) \cap K\}.$$

This theorem has an obvious interpretation for group algebras. In particular, assume R is a discrete valuation ring (DVR) with maximal ideal πR , and let G be a finite group of order n . Then n is also the order of the symmetric algebra RG . Assume that K is a splitting field for $KG = A$. Let e be a block idempotent of RG , and write $e = e_1 + \cdots + e_s$ as a sum of block idempotents of A . For each j , let d_j be the nonnegative integer such that $\pi^{d_j} R = (n/n_j)R$, where n_j^2 is the degree of $e_j A$ over its center K . Set $d = \max\{d_j: 1 \leq j \leq s\}$. Since K is a splitting field for A , each $R_j = R$ (in the notation of this section), so by the above theorem, $J_R(RG, e) = \bigcap_j \pi^{d_j} R = \pi^d R$. Note that d is the defect of the block idempotent e of RG as defined in Curtis and Reiner [2, § 86].

3. A generalization of the homological different. In this section we define certain ideals of Δ which are related to the homological different, and which

bear close resemblance to the ideals $J_\Delta(\Lambda, e)$ studied in the previous sections. Notation and assumptions of the previous sections will be retained. Recall that Λ is defined to be a separable R -algebra if Λ is a projective Λ^e -module. The reader is directed to Auslander and Goldman [1] for pertinent facts about separability.

The multiplication map $\epsilon: \Lambda^e \rightarrow \Lambda$ induces the map $\epsilon_*: \text{Hom}_{\Lambda^e}(\Lambda, \Lambda^e) \rightarrow \Delta$ by $\epsilon_*(f) = \epsilon(f(1))$, and the image $H_\Delta(\Lambda)$ of ϵ_* is called the *homological different* of Λ . It is easy to show that $H_\Delta(\Lambda) = \text{Ann}_\Delta(\text{Ext}_{\Lambda^e}^1(\Lambda, -))$, and $H_\Delta(\Lambda) \subseteq J_\Delta(\Lambda)$.

Definition. Let e be a central idempotent of A . Define $M_\Delta(\Lambda, e) = \bigcap_{\Lambda \subseteq \Gamma} \{\text{Ann}_\Delta(\text{Ext}_{\Lambda^e}^1(e\Gamma, -))\}$, where the intersection is taken over all R -orders Γ containing Λ . Set $M_\Delta(\Lambda) = M_\Delta(\Lambda, 1)$, and $M_R(\Lambda, e) = M_\Delta(\Lambda, e) \cap R$.

It is clear from the definition that $M_\Delta(\Lambda) \subseteq H_\Delta(\Lambda)$. Since separable orders are maximal [1, Proposition 7.1], it follows that $M_\Delta(\Lambda) = \Delta$ if and only if Λ is separable over R .

We have an obvious analogue to Theorem 1.2.

Theorem 3.1. *Let e be a central idempotent of A . Then $M_\Delta(\Lambda, e) = \{z \in \Delta: ze \in M_\Delta(\Lambda)\}$.*

Proof. To show the inclusion $\supseteq$, assume $z \in \Delta$ and $ze \in M_\Delta(\Lambda)$. Let Γ be an R -order containing Λ , and set $\Gamma_0 = e\Gamma + (1-e)\Gamma$. Then Γ_0 is an R -order containing Λ such that $e\Gamma_0 = e\Gamma$. Since $\text{Ext}_{\Lambda^e}^1(\Gamma_0, -) \cong \text{Ext}_{\Lambda^e}^1(e\Gamma, -) \oplus \text{Ext}_{\Lambda^e}^1((1-e)\Gamma, -)$, we see that $\text{Ann}_\Delta(\text{Ext}_{\Lambda^e}^1(e\Gamma, -)) \supseteq \text{Ann}_\Delta(\text{Ext}_{\Lambda^e}^1(\Gamma_0, -)) \supseteq M_\Delta(\Lambda)$, hence $ze \in \text{Ann}_\Delta(\text{Ext}_{\Lambda^e}^1(e\Gamma, -))$. Now the left multiplications λ_z and λ_{ze} on $e\Gamma$ are identical, so $z \in \text{Ann}_\Delta(\text{Ext}_{\Lambda^e}^1(e\Gamma, -))$. Thus $z \in M_\Delta(\Lambda, e)$.

For the inclusion $\subseteq$, fix $z \in M_\Delta(\Lambda, e)$. Then the left multiplication λ_z on $e\Lambda$ is projective, so essentially from Lemma 1.3 we see that $ze = \lambda_z(e) \in \Delta$. The remainder of the proof now parallels that of Theorem 1.2.

Corollary 3.2. *Let e be a central idempotent of A . Then $eM_\Delta(\Lambda) = eM_\Delta(\Lambda, e) \subseteq M_\Delta(\Lambda)$.*

Proof. Copy the proof of Corollary 1.5.

We proceed to give an explicit computation of $M_\Delta(\Lambda)$ in case Λ is a symmetric algebra.

Now R is a Dedekind domain, so Λ is finitely generated and projective over R , and the map $\gamma: \Lambda^e \rightarrow \text{Hom}_R(\Lambda^*, \Lambda)$ given by $\gamma(a \otimes b)(f) = af(b)$, for $a \otimes b \in \Lambda^e$, and for all $f \in \Lambda^* = \text{Hom}_R(\Lambda, R)$, is a (Λ^e, Λ^e) -bimodule isomorphism. Here $\text{Hom}_R(\Lambda^*, \Lambda)$ is a (Λ^e, Λ^e) -bimodule by defining $[(a \otimes b)\theta](f) = a\theta(bf)$ and $[\theta(a \otimes b)](f) = \theta(fb)a$, where $a \otimes b \in \Lambda^e$, $\theta \in \text{Hom}_R(\Lambda^*, \Lambda)$, and $f \in \Lambda^*$.

Let Γ be an R -order containing Λ , and consider the obvious Λ^e -homomorphism $\Lambda \rightarrow \Gamma$ given by inclusion. We obtain the commutative diagram

$$\begin{array}{ccc}
 \text{Hom}_{\Lambda^e}(\Gamma, \Lambda^e) \otimes_{\Lambda^e} \Gamma & \xrightarrow{\mu^!} & \text{Hom}_{\Lambda^e}(\Gamma, \Gamma) \\
 \uparrow \sigma^\Gamma & & \uparrow \tau^\Gamma \\
 \text{Hom}_{\Lambda^e}(\Gamma, \Lambda^e) & \xrightarrow{\epsilon_*^\Gamma} & \text{Hom}_{\Lambda^e}(\Gamma, \Lambda),
 \end{array}$$

where $\sigma^\Gamma(f) = f \otimes 1$, τ^Γ is induced from $\Lambda \rightarrow \Gamma$, ϵ_*^Γ is induced from the multiplication $\epsilon: \Lambda^e \rightarrow \Lambda$, and $[\mu^\Gamma(f \otimes x)](y) = f(y)x$. Note that τ^Γ is one-to-one.

Lemma 3.3 (Roggenkamp [6]). *The image of μ^Γ is the set of all projective Λ^e -endomorphisms of Γ .*

We may regard $\text{Hom}_{\Lambda^e}(\Gamma, \Lambda^e)$ as a right Λ^e -submodule of the right Λ^e -module $\text{Hom}_{\Lambda^e}(A, \Lambda^e)$. Since $\Gamma \rightarrow A^e$ given by $x \rightarrow x \otimes 1$ is a ring homomorphism, $\text{Hom}_{\Lambda^e}(A, \Lambda^e)$ becomes a right Γ -module.

Lemma 3.4. *Let Γ be an R -order containing Λ . If $\text{Hom}_{\Lambda^e}(\Gamma, \Lambda^e)\Gamma \subseteq \text{Hom}_{\Lambda^e}(\Gamma, \Lambda^e)$, then the restriction $\tau_0^\Gamma: \text{Im}(\epsilon_*^\Gamma) \rightarrow \text{Im}(\mu^\Gamma)$ of τ^Γ to $\text{Im}(\epsilon_*^\Gamma)$ is an isomorphism.*

Proof. It is clear that τ^Γ , and therefore τ_0^Γ , is one-to-one. The commutativity of the above diagram shows that τ_0^Γ maps into $\text{Im}(\mu^\Gamma)$; thus we only need to show that it is onto. Let $f \in \text{Hom}_{\Lambda^e}(\Gamma, \Lambda^e)$ and $x \in \Gamma$. Choose $0 \neq r \in R$ such that $rx \in \Lambda$. Then $r(f \otimes x) = f \otimes rx = f \otimes (rx \otimes 1)1 = f(rx \otimes 1) \otimes 1 = frx \otimes 1$ in $\text{Hom}_{\Lambda^e}(\Gamma, \Lambda^e) \otimes_{\Lambda^e} \Gamma$. Since $\text{Hom}_{\Lambda^e}(\Gamma, \Lambda^e)\Gamma \subseteq \text{Hom}_{\Lambda^e}(\Gamma, \Lambda^e)$, we have that $fx \in \text{Hom}_{\Lambda^e}(\Gamma, \Lambda^e)$, and so from above $r(f \otimes x) = r(fx \otimes 1)$ in $\text{Hom}_{\Lambda^e}(\Gamma, \Lambda^e) \otimes_{\Lambda^e} \Gamma$. Therefore $\tau \mu^\Gamma(f \otimes x) = \tau \mu^\Gamma(fx \otimes 1)$, and since $\text{Hom}_{\Lambda^e}(\Gamma, \Gamma)$ is R -torsion free, $\mu^\Gamma(f \otimes x) = \mu^\Gamma(fx \otimes 1) = \mu^\Gamma \sigma^\Gamma(fx) = \tau_0^\Gamma \epsilon_*^\Gamma(fx)$. It follows that τ_0^Γ is onto, as desired.

Remarks. (1) The hypotheses of the above lemma are clearly satisfied if $\Lambda = \Gamma$.

(2) The function $\text{Hom}_{\Lambda^e}(\Gamma, \Lambda) \rightarrow (\Lambda: \Gamma)_\Delta$ given by $g \rightarrow g(1)$ is an isomorphism, which we will regard as an identification; thus $\text{Im}(\epsilon_*^\Gamma) \subseteq (\Lambda: \Gamma)_\Delta$.

Lemma 3.5. *Let Γ be an R -order containing Λ . Assume (Λ, ϕ) is a symmetric R -algebra, and let $(a_i), (b_i)$ be dual bases of Λ with respect to ϕ . Then $\theta^\Gamma: (\Lambda: \Gamma)_\Delta \rightarrow \text{Hom}_{\Lambda^e}(\Gamma, \Lambda^e)$ defined by $\theta^\Gamma(a)(x) = \sum_i x b_i a_i \otimes a_i$ is a right Λ^e -isomorphism. In particular, $\text{Hom}_{\Lambda^e}(\Gamma, \Lambda^e)\Gamma \subseteq \text{Hom}_{\Lambda^e}(\Gamma, \Lambda^e)$.*

Proof. Define $\psi: \text{Hom}_{\Lambda^e}(\Gamma, \Lambda^e) \rightarrow (\Lambda: \Gamma)_\Delta$ by $\psi(f) = [\gamma(f(1))](\phi(1))$, where $\gamma: \Lambda^e \rightarrow \text{Hom}_R(\Lambda^*, \Lambda)$ is the isomorphism defined after Corollary 3.2. It is relatively routine to check that ψ is the inverse of θ^Γ , which shows that θ^Γ is an isomorphism. Now by Lemma 2.2, $(\Lambda: \Gamma)_\Delta \Gamma \subseteq (\Lambda: \Gamma)_\Delta$, so it follows that $\text{Hom}_{\Lambda^e}(\Gamma, \Lambda^e)\Gamma \subseteq \text{Hom}_{\Lambda^e}(\Gamma, \Lambda^e)$, as desired.

Let us continue to assume the hypotheses of Lemma 3.5. Now $\epsilon_*^\Gamma: \text{Hom}_{\Lambda^e}(\Gamma, \Lambda^e) \rightarrow (\Lambda: \Gamma)_\Delta$ is given by $\epsilon_*^\Gamma(g) = \epsilon g(1)$. By the lemma, $\theta^\Gamma: (\Lambda: \Gamma)_\Delta \rightarrow \text{Hom}_{\Lambda^e}(\Gamma, \Lambda^e)$ is given by $\theta^\Gamma(a)(x) = \sum_i x b_i a \otimes a_i$, so for any $a \in (\Lambda: \Gamma)_\Delta$, $\epsilon_*^\Gamma(\theta^\Gamma(a)) = \epsilon[\theta^\Gamma(a)(1)] = \sum_i b_i a a_i$. (Observe that $\epsilon_*^\Gamma \theta^\Gamma$ coincides with the Gaschütz-Ikeda operator [2, §71].) Since θ^Γ is an isomorphism, $\text{Im}(\epsilon_*^\Gamma \theta^\Gamma) = \text{Im}(\epsilon_*^\Gamma) \cong \text{Im}(\mu^\Gamma)$, by Lemmas 3.5 and 3.4. It is now easy to see that, for any $z \in \Delta$, the left multiplication λ_z on Γ is a projective Λ^e -endomorphism if and only if $z \in \text{Im}(\epsilon_*^\Gamma) = \text{Im}(\epsilon_*^\Gamma \theta^\Gamma)$, that is, if and only if $z = \sum_i b_i a a_i$ for some $a \in (\Lambda: \Gamma)_\Delta$. We therefore have

Lemma 3.6. *Let Γ be an R -order containing Λ , and let (Λ, ϕ) be a symmetric R -algebra with dual bases $(a_i), (b_i)$ for A with respect to ϕ . Then*

$$\text{Ann}_\Delta(\text{Ext}_{\Lambda^e}^1(\Gamma, -)) = \left\{ \sum_i b_i a a_i : a \in (\Lambda: \Gamma)_\Delta \right\}.$$

Corollary 3.7. *If (Λ, ϕ) is a symmetric R -algebra, then $M_\Delta(\Lambda) = \bigcap_{\Lambda \subseteq \Gamma} \{\text{Ann}_\Delta(\text{Ext}_{\Lambda^e}^1(\Gamma, -))\}$, where the intersection is over all maximal R -orders containing Λ .*

Proof. If Γ, Γ' are R -orders such that $\Lambda \subseteq \Gamma \subseteq \Gamma'$, then plainly $(\Lambda: \Gamma')_\Delta \subseteq (\Lambda: \Gamma)_\Delta$. By the above lemma, $\text{Ann}_\Delta(\text{Ext}_{\Lambda^e}^1(\Gamma', -)) \subseteq \text{Ann}_\Delta(\text{Ext}_{\Lambda^e}^1(\Gamma, -))$. The corollary now follows directly from the definition of $M_\Delta(\Lambda)$.

Lemma 3.8. *Let (Λ, ϕ) be a symmetric algebra of order c , and let $(a_i), (b_i)$ be dual bases for A with respect to ϕ . Then for any $a \in A$, $\sum_i b_i a a_i = \sum_j (c/n_j) U_j(a)$.*

Proof. Fix $a \in A$, and write $\sum_i b_i a a_i = \sum_k \alpha_k$, where each $\alpha_k \in K_k$, the center of A_k . By the discussion following Proposition 2.1, we have that $c = \sum_i a_i b_i$, and c belongs to Δ . Therefore for any j , $c U_j(a) = U_j(ca) = U_j(\sum_i a_i b_i a) = U_j(\sum_i b_i a a_i) = U_j(\sum_k \alpha_k) = U_j(\alpha_j) = \alpha_j n_j$. By dividing by n_j , this implies that $\alpha_j = (c/n_j) U_j(a)$, as desired.

Now let Γ be a maximal R -order containing Λ , and assume that (Λ, ϕ) is a symmetric R -algebra of order c , with dual bases $(a_i), (b_i)$ of A with respect to ϕ . By Lemma 2.2, $(\Lambda: \Gamma)_\Delta = \sum_j (c/n_j) d_{U_j}^{-1}(\Gamma_j) d_{T_j}^{-1}(R_j)$. Recall that $\epsilon_*^\Gamma \theta^\Gamma: a \rightarrow \sum_i b_i a a_i = \sum_j (c/n_j) U_j(a)$ as above. It follows that the image of $(\Lambda: \Gamma)_\Delta$ under $\epsilon_*^\Gamma \theta^\Gamma$ is

$$\sum_j (c/n_j)^2 d_{T_j}^{-1}(R_j) U_j(d_{U_j}^{-1}(\Gamma_j)).$$

Since R is a Dedekind domain, it is easy to see that $U_j(d_{U_j}^{-1}(\Gamma_j)) = R_j$. Therefore

$$\text{Im}(\epsilon_*^\Gamma \theta^\Gamma) = \sum_j (c/n_j)^2 d_{T_j}^{-1}(R_j).$$

Observe that this expression is independent of the maximal order Γ . We can now apply Lemma 3.6 and Corollary 3.7 to obtain the following characterization of $M_\Delta(\Lambda)$.

Theorem 3.9. *Let (Λ, ϕ) be a symmetric R -algebra of order c . Then $M_\Delta(\Lambda) = \sum_j (c/n_j)^2 d_{T_j}^{-1}(R_j)$. Furthermore, if e is a central idempotent in Λ , then*

$$eM_\Delta(\Lambda) = \sum_{e_j e = e_j} (c/n_j)^2 d_{T_j}^{-1}(R_j),$$

and

$$M_R(\Lambda, e) = \bigcap_{e_j e = e_j} \{(c/n_j)^2 d_{T_j}^{-1}(R_j) \cap K\}.$$

We can use this characterization of $M_\Delta(\Lambda)$ to give the following theorem about separability:

Theorem 3.10. *Let e be a central idempotent of Λ . Then the following statements are equivalent:*

- (a) $e \in \Lambda$ and $e\Lambda$ is separable over R ,
- (b) $e\Lambda$ is a projective Λ^e -module,
- (c) $M_\Delta(\Lambda, e) = \Delta$.

If in addition, (Λ, ϕ) is a symmetric algebra of order c , then these are equivalent to the following statement:

- (d) (c/n_j) is a unit in R_j for each j such that $e_j e = e_j$.

Proof. The proof of the equivalence of (a), (b) and (c) is left to the reader. Now assume (a), (b) and (c). Then $e\Lambda$ is a maximal R -order by [1, Proposition 7.1], and so R_j is the center of $e_j \Lambda$ for each j such that $e_j e = e_j$. Since each $e_j \Lambda$ is R -separable, it follows that R_j is R -separable [1, Theorem 2.3], and one can check in this case that $d_{T_j}^{-1}(R_j) = R_j$. By Theorem 3.9, $e\Lambda = eM_\Delta(\Lambda, e) = \sum_{e_j e = e_j} (c/n_j)^2 R_j$, and it follows that (c/n_j) is a unit in R_j for each j such that $e_j e = e_j$. This proves (d). Now assume (d). Fix a j such that $e_j e = e_j$, so that (c/n_j) is a unit in R_j ; since $(c/n_j)^2 d_{T_j}^{-1}(R_j)$ is an ideal in the domain R_j and (c/n_j) is a unit, it follows that $(c/n_j) R_j = d_{T_j}^{-1}(R_j) = R_j$. Therefore $M_R(\Lambda, e) = R$, and so $1 \in M_R(\Lambda, e)$. Thus $1 \in M_\Delta(\Lambda, e)$, and so $M_\Delta(\Lambda, e) = \Delta$, which shows that (d) implies (c). This completes the proof of the theorem.

We conclude this section with an explicit computation of $M_R(\Lambda)$ when Λ is the group algebra RG of a finite group G .

Proposition 3.11. *Let G be a finite group of order n . Then $M_R(RG) = n^2 R$.*

Proof. We have already observed that RG is a symmetric algebra of order n . It is clear from Theorem 3.9, that $M_R(RG) \supseteq n^2 R$. If e_1 is the block idempotent of

KG corresponding to the KG -module K with trivial G -action, then $n_1 = 1$ and $R_1 = R$. Therefore $(n/n_1)^2 d_{T_1}^{-1}(R_1) \cap K = n^2 R$. Theorem 3.9 now implies that $M_R(RG) \subseteq n^2 R$, and the corollary follows.

4. A characterization of separable orders. Assume, as in the previous sections, that R is a Dedekind domain with quotient field K , and that Λ is an R -order in the separable K -algebra A . If p is a maximal ideal of R , let R_p denote the localization of R at p . Similarly set $\Lambda_p = R_p \otimes_R \Lambda$. The main theorem of this section is the following characterization of separable orders.

Theorem 4.1. *The R -order Λ is separable over R if and only if the following statements hold:*

- (1) *the center $Z(\Lambda)$ of Λ is separable over R ,*
- (2) *Λ is a symmetric R -algebra,*
- (3) *the natural map $Z(\Lambda_p) \rightarrow Z(\Lambda_p/p\Lambda_p)$ is onto for each maximal ideal p of R .*

Proof. Assume first that Λ is separable over R . We have already observed that $Z(\Lambda)$ is separable over R , so (1) is established. Endo and Watanabe [3] have shown that Λ is a symmetric algebra, which proves (2). Now (3) follows immediately from the following.

Proposition 4.2. *For any R -order Λ in A , $\text{Ext}_{\Lambda^e}^1(\Lambda, \Lambda) = 0$ if and only if the natural map $Z(\Lambda_p) \rightarrow Z(\Lambda_p/p\Lambda_p)$ is onto for each maximal ideal p of R .*

Proof. Consider first the case where R is a DVR with maximal ideal πR , and set $\bar{\Lambda} = \Lambda/\pi\Lambda$. By applying the functor $\text{Hom}_{\Lambda^e}(\Lambda, -)$ to the exact sequence $0 \rightarrow \Lambda \xrightarrow{\pi} \Lambda \rightarrow \bar{\Lambda} \rightarrow 0$ of left Λ^e -modules, we see that $Z(\Lambda) \rightarrow Z(\bar{\Lambda}) \rightarrow \text{Ext}_{\Lambda^e}^1(\Lambda, \Lambda) \xrightarrow{\pi} \text{Ext}_{\Lambda^e}^1(\Lambda, \Lambda)$ is exact, where π is used here to denote multiplication. Now if $\text{Ext}_{\Lambda^e}^1(\Lambda, \Lambda) = 0$, it is clear that $Z(\Lambda) \rightarrow Z(\bar{\Lambda})$ is onto. Conversely, if $Z(\Lambda) \rightarrow Z(\bar{\Lambda})$ is onto, then $0 \rightarrow \text{Ext}_{\Lambda^e}^1(\Lambda, \Lambda) \xrightarrow{\pi} \text{Ext}_{\Lambda^e}^1(\Lambda, \Lambda)$ is exact; but this surely implies that $\text{Ext}_{\Lambda^e}^1(\Lambda, \Lambda) = 0$, since otherwise multiplication by π on the torsion R -module $\text{Ext}_{\Lambda^e}^1(\Lambda, \Lambda)$ would not be one-to-one.

For the general case, we need only observe that $\text{Ext}_{\Lambda^e}^1(\Lambda, \Lambda) \cong \bigoplus_p \text{Ext}_{\Lambda_p^e}^1(\Lambda_p, \Lambda_p)$, where the sum is over all maximal ideals p of R . This concludes the proof of the proposition.

Returning now to the proof of Theorem 4.1, assume that conditions (1), (2), and (3) hold. We must show that Λ is separable over R . By [1, Corollary 4.5], it is sufficient to show that Λ_p is separable over R_p for each maximal ideal p of R . We leave it to the reader to verify that conditions (1) and (2) imply their local versions. We may therefore assume that R is a DVR with maximal ideal

πR , $Z(\Lambda)$ is separable over R , Λ is a symmetric R -algebra, and the natural map $Z(\Lambda) \rightarrow Z(\Lambda/\pi\Lambda)$ is onto. It is easy to see that $\bar{\Lambda}$ is a symmetric $\bar{R}$ -algebra, where $\bar{R} = R/\pi R$ and $\bar{\Lambda} = \Lambda/\pi\Lambda$. Since $Z(\Lambda) \rightarrow Z(\bar{\Lambda})$ is onto, [1, Theorem 4.7] implies that $Z(\bar{\Lambda})$ is separable over the field $\bar{R}$. To show that Λ is separable over R , by [1, Theorem 4.7] it suffices to show that $\bar{\Lambda}$ is separable over $\bar{R}$. The proof is complete by establishing the following.

Theorem 4.3. *Let F be a field and let B be a symmetric F -algebra. Then B is semisimple if and only if its center $Z(B)$ is semisimple. Moreover, B is separable over F if and only if its center $Z(B)$ is separable over F .*

Proof. If B is semisimple, so is $Z(B)$. So assume conversely that $Z(B)$ is semisimple, and let J denote the radical of B . Then $J \cap Z(B) = 0$. By applying $\text{Hom}_{B^e}(B, _)$ to the exact sequence $0 \rightarrow J \rightarrow B \rightarrow B/J \rightarrow 0$ of left B^e -modules, we see that $0 \rightarrow J \cap Z(B) \rightarrow Z(B) \rightarrow Z(B/J)$ is exact. Since $J \cap Z(B) = 0$, the map $Z(B) \rightarrow Z(B/J)$ is one-to-one. Now dualize with respect to F by applying $\text{Hom}_F(_, F) = (_)^*$ to obtain the exact sequence $0 \rightarrow (B/J)^* \rightarrow B^* \rightarrow J^* \rightarrow 0$ of left B^e -modules. Now B/J is semisimple, so B/J is a symmetric F -algebra. It follows that $(B/J)^* \cong B/J$ as left B^e -modules, and $B^* \cong B$ as left B^e -modules by assumption. Thus we have an exact sequence $0 \rightarrow B/J \rightarrow B$. Again applying $\text{Hom}_{B^e}(B, _)$ we have that $0 \rightarrow Z(B/J) \rightarrow Z(B)$ is exact. It follows by counting dimensions, using the previously established monomorphism $Z(B) \rightarrow Z(B/J)$, that $Z(B/J) \rightarrow Z(B)$ is onto. Hence 1 is in the image of $B/J \rightarrow B$. Since this image is an ideal of B , the map $B/J \rightarrow B$ is an epimorphism. This is impossible unless $J = 0$, by counting dimensions. Hence B is semisimple. The remainder of the theorem now follows from the characterization of a separable F -algebra as an F -algebra which is semisimple and whose center is separable over F .

Corollary 4.4. *Let A be a central simple K -algebra. Then Λ is separable over R if and only if the following statements hold:*

- (1) Λ is a symmetric R -algebra,
- (2) the natural map $Z(\Lambda_p) \rightarrow Z(\Lambda_p/p\Lambda_p)$ is onto for each maximal ideal p of R .

Corollary 4.5. *Let e be a central idempotent of Λ , and assume Λ is a symmetric R -algebra such that the natural map $Z(\Lambda_p) \rightarrow Z(\Lambda_p/p\Lambda_p)$ is onto for each maximal ideal p of R . If K is a splitting field for eA , then the following statements are equivalent:*

- (a) $e\Lambda$ is separable over R .
- (a') $M_\Delta(\Lambda, e) = \Delta$.
- (b) $e\Lambda$ is hereditary.
- (b') $J_\Delta(\Lambda, e) = \Delta$.
- (c) $e_j \in \Lambda$ for all block idempotents e_j of A such that $e_j e = e_j$.

Proof. The equivalences (a) $\Leftrightarrow$ (a') and (b) $\Leftrightarrow$ (b') are routine. Clearly (a) implies (b), and (b) implies (c) by Corollary 1.4. We will prove that (c) implies (a). Let e_j be a block idempotent of A such that $e_j e = e_j$. Then $e_j \in \Lambda$, and $e_j A$ is K -central simple because K is a splitting field for eA . One checks that hypotheses (1) and (2) of Corollary 4.4 are satisfied by $e_j \Lambda$, since $e_j \in \Lambda$, and so $e_j \Lambda$ is separable over R . Since e is the sum of those block idempotents e_j of A such that $e_j e = e_j$, it follows that $e\Lambda$ is separable over R , completing the proof.

Observe that the above hypotheses are satisfied if Λ is the group algebra RG of a finite group G , and if K is a splitting field for KG . The corollary is false if K is not a splitting field: For example, $\mathbb{Z}[i]$ is a commutative, symmetric $\mathbb{Z}$ -order in the simple $\mathbb{Q}$ -algebra $\mathbb{Q}[i]$, where $i^2 = -1$, so (c) is clearly satisfied in the above corollary (with $e = 1$), but $\mathbb{Z}[i]$ is not separable over $\mathbb{Z}$.

Examples. (1) Let R be a DVR with maximal ideal πR and quotient field K , and let Λ be the set of all matrices of the form

$$\begin{pmatrix} a & \pi b \\ c & d \end{pmatrix}$$

for $a, b, c, d \in R$. Then Λ is a hereditary order in the central simple algebra $(K)_2$ of two-by-two matrices over K , but Λ is not maximal, hence it is not separable over R . One can check that $\bar{\Lambda} = \Lambda/\pi\Lambda$ is not a symmetric algebra (it is a Frobenius algebra), but $Z(\Lambda) \rightarrow Z(\bar{\Lambda})$ is onto. This shows that the hypothesis that Λ be symmetric cannot be deleted from Corollary 4.4.

(2) Now let $R = \mathbb{Z}_{(2)}$, the localization of the ring $\mathbb{Z}$ of integers at the maximal ideal (2), and let Λ be the R -algebra freely generated by $\{1, a, b, c\}$, subject to the following multiplication:

	1	a	b	c
1	1	a	b	c
a	a	-1	c	$-b$
b	b	$-c$	1	$-a$
c	c	b	a	1

One can check that Λ is a twisted group algebra over R of the Klein four-group G , with the obvious factor set. It follows that Λ is a symmetric algebra. Moreover, if K denotes the rational field, so that K is the quotient field of R , then $K \otimes_R \Lambda = A$ is a K -central simple algebra. Now the residue class algebra $\bar{\Lambda} = \Lambda/2\Lambda$ is the ordinary group algebra $\bar{R}G$ over $\bar{R} \cong \mathbb{Z}/(2)$, so $\bar{\Lambda}$ is not semisimple.

Hence Λ is not separable over R . It is obvious that Λ is noncommutative while $\overline{\Lambda}$ is commutative, so $Z(\Lambda) \rightarrow Z(\overline{\Lambda})$ is not onto. This shows that condition (2) of Corollary 4.4 cannot be deleted.

Using [3], the proof of Theorem 4.1 may be modified to apply in case Λ is a finitely generated projective faithful algebra over an arbitrary commutative ring R .
