SIMULTANEOUS APPROXIMATION OF ADDITIVE FORMS

BY

MING-CHIT LIU

ABSTRACT. Let $X = (x_1, \dots, x_s)$ be a vector of s real components and $f_i(X) = \sum_{j=1}^s \theta_{ij} x_j^k$ ($k = 2, 3, \dots$; $i = 1, \dots, R$) R additive forms, where θ_{ij} are arbitrary real numbers. The author obtains some results on the simultaneous approximation of $\|f_i(X)\|$, where $\|t\|$ means the distance from t to the nearest integer.

1. Introduction. In 1948 Heilbronn [5] improved Vinogradov's result [9] and obtained that for any $\epsilon > 0$ there exists some positive constant $C = C(\epsilon)$ which depends on ϵ only such that for any real number θ and any integer $N \geq 1$ there is an integer x satisfying

$$(1.1) \quad 1 \leq x \leq N \quad \text{and} \quad \|\theta x^2\| < CN^{-1/2+\epsilon},$$

where $\|t\|$ means the distance from t to the nearest integer.

In 1967, see [4], Davenport generalized (1.1) and obtained

$$(1.2) \quad 1 \leq x \leq N \quad \text{and} \quad \|\theta x^k\| < CN^{-(1/K)+\epsilon},$$

where $K = 2^{k-1}$, $k = 2, 3, \dots$ and $C = C(\epsilon, k)$ is a positive constant depending on ϵ, k only. Recently, R. J. Cook [2] extended (1.2) to a finite number of θ 's. On the other hand, Cook [3] and the author [8] obtained some results on additive forms. These results are as follows:

THEOREM C [2]. For any $\epsilon > 0$ and any integers $k > 1, R > 0$, there exists a positive constant $C = C(\epsilon, k, R)$ depending on ϵ, k, R only such that for any real numbers $\theta_1, \dots, \theta_R$ and any integer $N \geq 1$ there is an integer x satisfying

$$(1.3) \quad 1 \leq x \leq N \quad \text{and} \quad \max_{1 \leq i \leq R} (\|\theta_i x^k\|) < CN^{-(1/f(k, R))+\epsilon},$$

where $f(k, R)$ is defined by $K = 2^{k-1}$ and

$$(1.4) \quad f(k, 1) = K, \quad f(k, R) = 2f(k, R-1) + KR + 1 \quad (R \geq 2).$$

THEOREM L [8]. For any integers $k \geq 2$ and $s \geq 1$, put $K = 2^{k-1}$ and $X = (x_1, \dots, x_s)$, a vector of s real components. Let $f(X), g(X)$ be any two additive forms of degree k in s variables,

Key words and phrases. Additive form, Diophantine approximation, simultaneous approximation, asymptotic behaviour.

$$f(X) = \sum_{i=1}^s \theta_i x_i^k, \quad g(X) = \sum_{i=1}^s \phi_i x_i^k,$$

where $\theta_1, \dots, \theta_s; \phi_1, \dots, \phi_s$ are arbitrary real numbers. Then for any $\epsilon > 0$ and any integer $N \geq 1$ there are integers $x_1, \dots, x_s$ not all zero and some positive constant $C = C(\epsilon, k, s)$ which depends on ϵ, k, s only such that

$$(1.5) \quad 1 \leq \max_{1 \leq i \leq s} |x_i| \leq N,$$

$$\max(\|f(X)\|, \|g(X)\|) < CN^{-(1/F(k,s)) + \epsilon},$$

where

$$(1.6) \quad F(k, s) = \begin{cases} 7 & \text{if } s = 1, k = 2, \\ 3K + 1/k & \text{if } s = 1, k \geq 3, \\ 2K + 1 + K/ks & \text{if } s \geq 2. \end{cases}$$

In this paper we shall extend Theorem L to a finite number of additive forms with some improvements of Theorem C. We shall prove

THEOREM 1. For any integers $k \geq 2$ and $s \geq 1$, put $K = 2^{k-1}$ and $X = (x_1, \dots, x_s)$, a vector of s real components. For any integer $R \geq 3$ let

$$f_i(X) = \sum_{j=1}^s \theta_{ij} x_j^k \quad (i = 1, \dots, R)$$

be any R additive forms of degree k in s variables, where θ_{ij} ($i = 1, \dots, R; j = 1, \dots, s$) are arbitrary real numbers. Then for any $\epsilon > 0$ and any integer $N \geq 1$ there are integers $x_1, \dots, x_s$ not all zero and some positive constant $C = C(\epsilon, k, s, R)$ which depends on ϵ, k, s, R only such that

$$(1.7) \quad 1 \leq \max_{1 \leq j \leq s} |x_j| \leq N,$$

$$\max_{1 \leq i \leq R} (\|f_i(X)\|) < CN^{-(1/G(k,s,R)) + \epsilon},$$

where $G(k, s, R)$ is defined by

$$(1.8) \quad G(k, s, R) = 2g(k, R-1) + (R-1)K/ks + 1 \quad (R \geq 3)$$

and $g(k, R)$ is defined by

$$(1.9) \quad g(k, 2) = \begin{cases} 7 & \text{if } k = 2, \\ 3K + 1/k & \text{if } k \geq 3. \end{cases}$$

$$g(k, R) = 2g(k, R-1) + (R-1)K/k + 1 \quad (R \geq 3).$$

COROLLARY 1. For any $\epsilon > 0$ and any integers $k > 1, R > 1$ there exists a positive constant $C = C(\epsilon, k, R)$ depending on ϵ, k, R only such that for any

real numbers $\theta_1, \dots, \theta_R$ and any integer $N \geq 1$ there is an integer x satisfying

$$(1.10) \quad 1 \leq x \leq N \quad \text{and} \quad \max_{1 \leq i \leq R} (\|\theta_i x^k\|) < CN^{-(1/g(k,R)) + \epsilon},$$

where $g(k, R)$ is defined by (1.9).

Corollary 1 follows from Theorem L ($R = 2$) and Theorem 1 ($R \geq 3$).

We shall give the explicit form of $g(k, R)$ in Lemma 1 ((2.1), (2.2)) for the sake of application. For example when $k \geq 3$ we have:

R	$g(k, R)$
2	$3K + 1/k$
3	$(6 + 2/k)K + 1 + 2/k$
4	$(12 + 7/k)K + 3 + 4/k$
5	$(24 + 18/k)K + 7 + 8/k$
.....	

I wish to thank the referee for his very helpful suggestions which brought improvements on the presentation of this paper.

2. Notation and preliminary lemmas. In what follows k, s, R are the integers given in Theorem 1. We always assume that ϵ is a small enough positive quantity which is not the same ϵ given in Theorem 1 and that N is a sufficiently large positive integer, say $N > N_0 = N_0(\epsilon, k, s, R)$ which is a positive integer depending on ϵ, k, s, R given, such that all the subsequent asymptotic approximations and inequalities in §§3, 4 are satisfied. So it is difficult to define ϵ and N_0 at the beginning or at any particular point. If $y > 0$ we use $x \ll y$ to denote $|x| < Cy$, where C is some positive constant which can depend on ϵ, k, s, R . $[t]$ is the integral part of t . For real t we write $e(t) = \exp(2\pi ti)$. We shall use B to denote some irrelevant numbers which need not be the same from one occurrence to another. For figures $x, y, (x)_y$ indicates the y th formula in (x) .

We need several lemmas.

LEMMA 1. Let k, R be positive integers and $K = 2^{k-1}$. If

$$g(k, R) = 2g(k, R-1) + K(R-1)/k + 1 \quad (R \geq 3),$$

where

$$g(k, 2) = \begin{cases} 7 & \text{if } k = 2, \\ 3K + 1/k & \text{if } k \geq 3, \end{cases}$$

then

$$(2.1) \quad g(2, R) = (11)2^{R-2} - (R + 2),$$

$$(2.2) \quad g(k, R) = \left(3K + \frac{3K + k + 1}{k}\right)2^{R-2} - K\left(\frac{R+1}{k} + \frac{1}{K}\right) \quad \text{if } k \geq 3.$$

PROOF. Since for $R \geq 3, k \geq 2$ we have

$$g(k, R) = 2^{R-2}g(k, 2) + \sum_{i=0}^{R-3} 2^i + \frac{K}{2k} \sum_{i=1}^{R-2} (R-i)(2^i),$$

then (2.1), (2.2) follow by a simple calculation.

LEMMA 2. Suppose that Δ satisfies $0 < \Delta < \frac{1}{2}$ and r is a positive integer. Then there exists a real valued function $\psi(x)$, periodic with period 1, which satisfies

$$(2.3) \quad \begin{aligned} \psi(x) &= 0 \quad \text{if } \|x\| > \Delta, \\ \psi(x) &= \sum_{u=-\infty}^{\infty} c_u e(ux), \end{aligned}$$

where c_u are real and

$$(2.4) \quad c_0 = \Delta, \quad |c_u| < C(r) \min(\Delta, \Delta^{-r} |u|^{-r-1}) \quad \text{if } u \neq 0,$$

where $C(r)$ is some positive constant depending on r only.

PROOF. This is a particular case of Lemma 12 in [10, p. 32] with $\beta = -\alpha = \frac{1}{2}\Delta$.

LEMMA 3. Let $T = \sum_{x=1}^N e(tx^k)$, where $k = 2, 3, \dots$ and t is any real number. For any $\epsilon > 0$ we have

$$(2.5) \quad |T|^K \ll N^{K-1} + N^{K-k+\epsilon} \sum_{j=1}^L \min(N, 1/\|jt\|),$$

where $K = 2^{k-1}$ and $L = k!N^{k-1}$.

PROOF. See Satz 266 in [7, p. 255].

LEMMA 4. For any real t if there are integers a, q with $q > 0$ such that $(a, q) = 1$ and $|t - a/q| \leq q^{-2}$, then for any positive integers P and N ,

$$(2.6) \quad \sum_{j=P+1}^{P+q} \min(N, 1/\|jt\|) \ll N + q \log q.$$

PROOF. Lemma 4 is well known. See, for example, Lemma 3.5 in [6].

LEMMA 5. For any integer $k \geq 2$ put $K = 2^{k-1}$. For any ϵ with $0 < \epsilon < 1$ and any integers $s \geq 1, R \geq 3$ let λ satisfy

$$(2.7) \quad \lambda \{2g(k, R-1) + (R-1)K/sk + 1\} < 1 - \epsilon$$

and

$$(2.8) \quad \alpha = \frac{2}{K} g(k, R-1) + \frac{(R-1)(1-k)}{sk} + \frac{1}{K},$$

where $g(k, R)$ is defined by (1.9). Then the following five inequalities hold simultaneously.

$$(2.9) \quad (\lambda/s)RK < 1 - \epsilon,$$

$$(2.10) \quad (\lambda/s)(sK\alpha + (R-1)K) < 1 - \epsilon,$$

$$(2.11) \quad (\lambda/(k-1)s)(K(1+R^2) + sR - s\alpha K) < 1 - \epsilon,$$

$$(2.12) \quad (\lambda/(k-1))(2kg(k, R-1) - \alpha K + k) < 1 - \epsilon,$$

$$(2.13) \quad \lambda(2g(k, R-1) + 1) < 1 - \epsilon.$$

PROOF. By (1.9) it is easy to see that $g(k, R-1) > KR$ ($R = 3, 4, \dots$). It follows that $(2.7) \Rightarrow (2.13) \Rightarrow (2.9)$. On the other hand, substituting (2.8) into (2.10) and (2.12) we see that $(2.7) = (2.10) = (2.12)$. So it remains to show that when $R \geq 3$

$$(2.14) \quad 2kg(k, R-1) + k > K(1+R^2) + R,$$

i.e. $(2.12) \Rightarrow (2.11)$. Here we only give the arguments for $k \geq 3$. By (2.2) we have

$$2kg(k, R-1) + k = 3K(2^{R-2})(k+1) + k(2^{R-2} - 1) + 2^{R-2} - 2KR.$$

Then (2.14) follows since when $k \geq 3, R \geq 3$ we have

$$3(2^{R-2})(k+1) > (1+R)^2 \quad \text{and} \quad k(2^{R-2} - 1) + 2^{R-2} > R.$$

The proof of Lemma 5 is complete.

LEMMA 6. Let R, N be any positive integers and $\theta_1, \dots, \theta_R$ any real numbers. Then there exists an integer n satisfying

$$(2.15) \quad 1 \leq n \leq N, \quad \|\theta_i n\| < N^{-1/R} \quad (i = 1, \dots, R).$$

PROOF. See Theorem VI [1, p. 13].

3. Existence of an R -tuple. We come now to the proof of our theorem.

Suppose that for some $\lambda > 0$ there are no integral solutions $X = (x_1, \dots, x_s)$ of the following inequalities:

$$(3.1) \quad 1 \leq \max_{1 \leq j \leq s} |x_j| \leq N, \quad \max_{1 \leq i \leq R} (\|f_i(X)\|) \leq N^{-\lambda},$$

i.e. for each X with integers $x_1, \dots, x_s$ satisfying $1 \leq \max_{1 \leq j \leq s} |x_j| \leq N$, we have some i ($1 \leq i \leq R$) such that $\|f_i(X)\| > N^{-\lambda}$. Putting $\Delta = N^{-\lambda}$ in Lemma 2, we have

$$\begin{aligned}
 0 &= \sum_X \psi(f_1(X)) \cdots \psi(f_R(X)) \\
 (3.2) \quad &= \sum_X \left\{ \sum_{m_1=-\infty}^{\infty} c_{m_1} e(m_1 f_1(X)) \cdots \sum_{m_R=-\infty}^{\infty} c_{m_R} e(m_R f_R(X)) \right\} \\
 &= N^s c_0^R + \sum_X \sum_{\mathbf{m}} c_{m_1} \cdots c_{m_R} e \left(m_1 \sum_{j=1}^s \theta_{1j} x_j^k \right) \cdots e \left(m_R \sum_{j=1}^s \theta_{Rj} x_j^k \right),
 \end{aligned}$$

where Σ_X is taken over integers x_j with $1 \leq j \leq s$, $1 \leq x_j \leq N$, and $\Sigma_{\mathbf{m}}$ is taken over $-\infty < m_1, \dots, m_R < \infty$ except $\mathbf{m} = (m_1, \dots, m_R) = (0, \dots, 0)$. By (2.4) with $c_0 = N^{-\lambda}$ and (3.2) we have

$$(3.3) \quad N^{s-R\lambda} \leq \sum_{\mathbf{m}} |c_{m_1} \cdots c_{m_R}| \prod_{j=1}^s |S(\mathbf{m}, j)|,$$

where

$$(3.4) \quad S(\mathbf{m}, j) = \sum_{x=1}^N e \left(x^k \sum_{i=1}^R \theta_{ij} m_i \right) \quad (j = 1, \dots, s).$$

Write

$$(3.5) \quad \sum_{\mathbf{m}} |c_{m_1} \cdots c_{m_R}| \prod_{j=1}^s |S(\mathbf{m}, j)| = \left(\sum_1 + \sum_2 \right) |c_{m_1} \cdots c_{m_R}| \prod_{j=1}^s |S(\mathbf{m}, j)|,$$

where Σ_1 is the summation taken over $|m_i| < N^{\lambda+\epsilon}$ ($i = 1, \dots, R$) and $\mathbf{m} \neq (0, \dots, 0)$ while Σ_2 is taken over all remaining terms in $\Sigma_{\mathbf{m}}$. We are going to show that $\Sigma_2 \ll N^{s-R\lambda-\epsilon}$ if we let r given in Lemma 2 satisfy $r > R(\lambda + \epsilon)/\epsilon$. So in view of (3.3), (3.5) we may neglect Σ_2 .

For each $l = 1, \dots, R$ by (2.4)₂ we have

$$\begin{aligned}
 \sum_{|m_l| < \infty} |c_{m_l}| &= \sum_{|m_l| < N^{\lambda+\epsilon}} |c_{m_l}| + \sum_{|m_l| \geq N^{\lambda+\epsilon}} |c_{m_l}| \\
 (3.6) \quad &\ll N^{-\lambda} \sum_{|m_l| < N^{\lambda+\epsilon}} 1 + N^{r\lambda} \sum_{|m_l| \geq N^{\lambda+\epsilon}} |m_l|^{-r-1} \\
 &\ll N^{\epsilon} + N^{r\lambda} N^{-r(\lambda+\epsilon)} \ll N^{\epsilon}.
 \end{aligned}$$

Since by (3.4), $|S(\mathbf{m}, j)| \leq N$ we see that

$$\begin{aligned} \Sigma_2 &\leq \sum_{i=1}^R \left\{ \sum_{|m_i| \geq N^{\lambda+\epsilon}} |c_{m_1} \cdots c_{m_R}| \prod_{j=1}^s |S(m, j)| \right\} \\ &\leq N^s \sum_{i=1}^R \left\{ \sum_{|m_i| \geq N^{\lambda+\epsilon}} |c_{m_i}| \right\} \left\{ \prod_{i \neq l} \sum_{|m_l| < \infty} |c_{m_l}| \right\}. \end{aligned}$$

By (3.6) we have

$$\begin{aligned} \Sigma_2 &\leq N^s \sum_{i=1}^R \left\{ \sum_{|m_i| \geq N^{\lambda+\epsilon}} |c_{m_i}| \right\} N^{(R-1)\epsilon} \\ &\leq N^{s+(R-1)\epsilon} \sum_{i=1}^R N^{-r\epsilon} \leq N^{s+(R-1)\epsilon-r\epsilon} \leq N^{s-R\lambda-\epsilon}, \end{aligned}$$

if $r > R(\lambda + \epsilon)/\epsilon$.

It follows from (3.3), (3.5) (2.4)₂ that

$$\begin{aligned} N^{s-R\lambda} &\leq \sum_1 |c_{m_1} \cdots c_{m_R}| \prod_{j=1}^s |S(m, j)| \\ &\leq \sum_1 N^{-R\lambda} \prod_{j=1}^s |S(m, j)|. \end{aligned}$$

That is

$$(3.7) \quad N^s \leq \sum_1 \prod_{j=1}^s |S(m, j)| \leq \sum_{j=1}^s \sum_1 |S(m, j)|^s.$$

We see that there exists some j_0 ($1 \leq j_0 \leq s$) for which we write $\theta_i = \theta_{ij_0}$ and $S(m) = S(m, j_0)$, such that

$$(3.8) \quad N^s \leq \sum_1 |S(m)|^s,$$

where, by (3.4),

$$(3.9) \quad S(m) = \sum_{x=1}^N e \left(x^k \sum_{i=1}^R m_i \theta_i \right).$$

By definition of the notation $\leq$ there is some positive constant B such that we may rewrite (3.8) as

$$(3.8a) \quad BN^s \leq \sum_1 |S(m)|^s.$$

We are now going to show that by (3.8a) there exists a ρ

$$(3.10) \quad 0 \leq \rho \leq \lambda + \epsilon$$

such that

$$(3.11) \quad |S(m)| \geq (2^{-R-1}B)^{1/s} N^{1-R\rho} \quad (\gg N^{1-R\rho}),$$

$$p = \rho/s,$$

for at least $[N^{R\rho-\epsilon}] + 1$ R -tuples $(m_1, \dots, m_R)$ in

$$(3.12) \quad |m_i| < N^{\lambda+\epsilon} \quad (i = 1, \dots, R).$$

Suppose that such a ρ does not exist. For some integer l with $l\epsilon > 2R(\lambda + \epsilon)$ write

$$\sum_1 |S(m)|^s = \sum_3 |S(m)|^s + \sum_{j=0}^{l-1} T_j,$$

where Σ_3 is taken over $|m_i| < N^{\lambda+\epsilon}$ ($i = 1, \dots, R$), $m \neq (0, \dots, 0)$ and $|S(m)|^s < 2^{-R-1}BN^{s-R(\lambda+\epsilon)}$ while $T_j = \Sigma |S(m)|^s$ which are taken over $|m_i| < N^{\lambda+\epsilon}$ ($i = 1, \dots, R$), $m \neq (0, \dots, 0)$ and

$$2^{-R-1}BN^{(s-(j+1)R(\lambda+\epsilon)/l)} \leq |S(m)|^s < 2^{-R-1}BN^{(s-jR(\lambda+\epsilon)/l)}.$$

According to our assumption on ρ there are no such terms $|S(m)|^s$ satisfying $2^{-R-1}BN^s \leq |S(m)|^s$ even if $2^{-R-1}B < 1$. So we neglect this possibility in the above summation $\Sigma_{j=0}^{l-1} T_j$. Now by our supposition on ρ and $\epsilon/2 > R(\lambda + \epsilon)/l$ we have

$$T_j \leq (2^{-R-1}BN^{(s-jR(\lambda+\epsilon)/l)})(N^{(j+1)R(\lambda+\epsilon)/l-\epsilon})$$

$$= 2^{-R-1}BN^{(s-\epsilon+R(\lambda+\epsilon)/l)} < 2^{-R-1}BN^{s-\epsilon/2} \quad (j = 0, 1, \dots, l-1).$$

$$\sum_3 |S(m)|^s < (2^{-R-1}BN^{s-R(\lambda+\epsilon)})(2N^{\lambda+\epsilon})^R = BN^s/2.$$

Hence

$$\sum_1 |S(m)|^s = \sum_3 |S(m)|^s + \sum_{j=0}^{l-1} T_j$$

$$< (BN^s/2) + (2^{-R-1}BLN^{s-\epsilon/2}) < BN^s$$

if N is large. This contradicts (3.8a). So a ρ satisfying (3.10), (3.11) exists.

In what follows we shall confine our attention to the R -tuples $(m_1, \dots, m_R)$ satisfying (3.10), (3.11), (3.12). From (2.5), (3.9) we have

$$(3.13) \quad |S(m)|^K \leq N^{K-1} + N^{K-k+\epsilon} \sum_{j=1}^L \min(N, 1/\|j\|t),$$

where $L = k!N^{k-1}$ and

$$(3.14) \quad t = \sum_{i=1}^R \theta_i m_i.$$

Define

$$(3.15) \quad Q = N^{k-1+\alpha\lambda K-Kp} \quad (p = \rho/s),$$

where

$$(3.16) \quad \alpha = \alpha(k, s, R) = \frac{2}{K}g(k, R-1) + \frac{(R-1)(1-k)}{ks} + \frac{1}{K}$$

and $g(k, R)$ is defined by (1.9). By Dirichlet's theorem for given t and Q ((3.14), (3.15)) there are integers a, q such that

$$(3.17) \quad (a, q) = 1, \quad 1 \leq q \leq Q, \quad |qt - a| < Q^{-1}.$$

Fix such a q and divide the sum in the right of (3.13) into blocks of q terms. It follows from Lemma 4 and (3.13) that

$$|S(m)|^K \leq N^{K-1} + N^{K-k+\epsilon}(k!N^{k-1}q^{-1} + 1)(N + q \log q).$$

Then by (3.11) we have

$$(3.18) \quad N^{1-RKp-\epsilon} \leq Nq^{-1} + N^\epsilon + N^{1-k+\epsilon}q.$$

Suppose that λ satisfies

$$(3.19) \quad \lambda \left\{ 2g(k, R-1) + \frac{(R-1)K}{sk} + 1 \right\} < 1 - A\epsilon \quad (R \geq 3),$$

where $g(k, R)$ is defined by (1.9) and A is a positive constant. The value of A is so defined such that all following inequalities (3.21), (3.22), (3.26), (4.8), (4.10) will be satisfied.

By (3.15), (3.17)₂, (3.18) we have

$$(3.20) \quad q^{-1} \geq N^{-RKp-\epsilon} \{1 - N^{2\epsilon+RKp-1} - N^{RKp+2\epsilon-1+\alpha\lambda K-Kp}\}.$$

The last two terms in the curly bracket of (3.20) can be neglected since by (3.10), (3.19) and Lemma 5 ((2.9), (2.10)) we have

$$(3.21) \quad 2\epsilon + RKp - 1 < 0$$

and

$$(3.22) \quad RKp + 2\epsilon - 1 + \alpha\lambda K - Kp < 0.$$

Then from (3.20) we have

$$(3.23) \quad (1 \leq) q \leq N^{RKp+\epsilon}.$$

By Lemma 6, for given $\theta_1, \dots, \theta_R$ and integer $[QN^{-\epsilon}]$ there are integers $a_1, \dots, a_R$ and b such that

$$(3.24) \quad 1 \leq b \leq [QN^{-\epsilon}], \quad |b\theta_i - a_i| < [QN^{-\epsilon}]^{-1/R} \quad (i = 1, \dots, R).$$

It follows from (3.12), (3.14), (3.17)₃, (3.23) that

$$\begin{aligned}
 (3.25) \quad & \left| q \sum_{i=1}^R a_i m_i - ab \right| \leq q \sum_{i=1}^R |m_i| |a_i - \theta_i b| + b \left| q \left(\sum_{i=1}^R \theta_i m_i \right) - a \right| \\
 & \ll N^{RKp+\epsilon} \sum_{i=1}^R N^{\lambda+\epsilon} [QN^{-\epsilon}]^{-1/R} + [QN^{-\epsilon}] Q^{-1}.
 \end{aligned}$$

By (3.10), (3.19) and Lemma 5 ((2.11)) we see that

$$\begin{aligned}
 (3.26) \quad & (RKp + \epsilon) + (\lambda + \epsilon) - \frac{1}{R}(k - 1 + \alpha\lambda K - Kp - \epsilon) \\
 & < \frac{(k-1)}{R} \left\{ \frac{\lambda}{s(k-1)} (K(1+R^2) + sR - s\alpha K) + 1 + B\epsilon \right\} < -\epsilon,
 \end{aligned}$$

where B is some number depending on k, s, R only. Then from (3.15), (3.25), (3.26) we have $|q \sum_{i=1}^R a_i m_i - ab| \ll N^{-\epsilon} < 1$, for large N . That is $q \sum_{i=1}^R a_i m_i = ab$. But by (3.17)₁ $((a, q) = 1)$ we see that q divides b . Then by (3.15), (3.24)₁ the number of possibilities for q is $O(N^\epsilon)$. Since at least $[N^{R\rho-\epsilon}] + 1 (> 1)$ R -tuples $(m_1, \dots, m_R)$ in (3.12) satisfy (3.11) then $\gg N^{R\rho-2\epsilon}$ (or $\gg BN^{R\rho-2\epsilon}$ for some positive constant B) of these R -tuples have the same q . Choose a suitable d ($d^R B \geq 2^{R+1}$, say) such that the following pigeonhole argument holds. Partition the R -cube, $|m_i| \leq N^{\lambda+\epsilon}$ ($i = 1, \dots, R$) by

$$(3.27) \quad |m_i| = ldN^{\lambda+\epsilon-(\rho-(2\epsilon/R))},$$

where $i = 1, \dots, R; l = 0, 1, \dots$. In all, there are at most

$$\left(\frac{2N^{\lambda+\epsilon}}{dN^{\lambda+\epsilon-(\rho-(2\epsilon/R))}} \right)^R = (2/d)^R N^{R\rho-2\epsilon}$$

R -subcubes in the R -cube, $|m_i| \leq N^{\lambda+\epsilon}$ ($i = 1, \dots, R$). Now by the pigeonhole argument, there is an R -subcube containing at least two distinct R -tuples $(m'_1, \dots, m'_R), (m''_1, \dots, m''_R)$, say, having the same q . For these two R -tuples we may suppose that for some integer I with $1 \leq I \leq R$ we have $m'_I > m''_I$. Put

$$(3.28) \quad m_i = m'_i - m''_i \quad (i = 1, \dots, R).$$

In particular, we have

$$(3.29) \quad m_I \geq 1.$$

Then by (3.27), (3.28) and (3.17)₃ we have

$$(3.30) \quad |m_i| \leq N^{\lambda+\epsilon(1+(2/R))-\rho} \quad (i = 1, \dots, R).$$

$$\left\| \left(\sum_{i=1}^R \theta_i m_i \right) q \right\| \leq \left\| \sum_{i=1}^R \theta_i m'_i q \right\| + \left\| \sum_{i=1}^R \theta_i m''_i q \right\| < 2Q^{-1},$$

since R -tuples $(m'_1, \dots, m'_R), (m''_1, \dots, m''_R)$ have the same q in (3.17)₃.

4. Completion of the proof. In what follows we shall confine our attention to the new R -tuple $(m_1, \dots, m_R)$ satisfying (3.28), (3.30). We proceed by induction on R . As usual, our proof consists of two parts. We first show that Theorem 1 is true for $R (\geq 4)$ if we assume that Theorem 1 is true for $R - 1$. Then we can see that in fact Theorem 1 holds for $R = 3$.

Put

$$(4.1) \quad \phi_i = m_I^{k-1} q^k \theta_i,$$

$$(4.2) \quad M = [N^{(2\lambda + 2\epsilon(1+R^{-1}) - \rho)g/(1-\epsilon g)}],$$

where $g = g(k, R - 1)$, $i = 1, \dots, R$; $R \geq 3$. Suppose that Theorem 1 is true for $R - 1 (\geq 3)$. Then by Corollary 1, (1.10) is true for M and any $R - 1$ ϕ 's among $\phi_1, \dots, \phi_R$. So there is some integer n satisfying

$$1 \leq n \leq M,$$

$$(4.3) \quad \max_{1 \leq i \leq R; i \neq I} (\|\phi_i n^k\|) \ll M^{(-1/g(k, R-1)) + \epsilon} \ll N^{-2\lambda - 2\epsilon(1+R^{-1}) + \rho}.$$

Let

$$(4.4) \quad x = n q m_I.$$

It follows from (4.1), (4.3)₂, (3.30)₁ that

$$\|\theta_i x^k\| \leq \|(m_I^{k-1} q^k \theta_i) n^k\| m_I = \|\phi_i n^k\| m_I \quad (i = 1, \dots, R; R \geq 4)$$

and

$$(4.5) \quad \max_{1 \leq i \leq R; i \neq I} \|\theta_i x^k\| \ll N^{-2\lambda - 2\epsilon(1+R^{-1}) + \rho} N^{\lambda + \epsilon(1+(2/R)) - \rho} \ll N^{-\lambda - \epsilon}.$$

Similarly, we have

$$(4.6) \quad \begin{aligned} \|\theta_I x^k\| &= \|\theta_I n^k q^k m_I^k\| \\ &\leq q^{k-1} n^k m_I^{k-1} \left\| q \left(\sum_{i=1}^R \theta_i m_i \right) \right\| + \sum_{i=1; i \neq I}^R |m_i| \|(q^k m_I^{k-1} \theta_i) n^k\| \\ &\ll N^{\sigma_1} + N^{-\lambda - \epsilon}, \end{aligned}$$

where σ_1 is defined (so as to make the last part of (4.6) valid) by the first part of (4.7). By (3.23), (4.2), (3.30), (3.15) we see that

$$(4.7) \quad \begin{aligned} \sigma_1 &= (k-1)(RKp + \epsilon) + k(2\lambda + 2\epsilon(1+R^{-1}) - \rho)g/(1-\epsilon g) \\ &\quad + (k-1)(\lambda + \epsilon(1+(2/R)) - \rho) - (k-1 + \alpha\lambda K - Kp) \\ &= p((k-1)RK - skg - (k-1)s + K) \\ &\quad + \lambda(2kg - \alpha K + k) + B\epsilon - (k-1) - \lambda - \epsilon, \end{aligned}$$

where B depends on k, R only. As pointed out in the proof of Lemma 5, $g(k, R-1) = g > KR$ when $R \geq 4$, whence we see that $(k-1)RK - skg - (k-1)s + K < 0$. Then together with (4.7), (3.19), and Lemma 5 ((2.12)), we have

$$(4.8) \quad \sigma_1 < \lambda(2kg(k, R-1) - \alpha K + k) - (k-1) + B\epsilon - \lambda - \epsilon < -\lambda - \epsilon.$$

Hence by (4.5), (4.6), (4.8) we have

$$(4.9) \quad \max_{1 \leq i \leq R} \|\theta_i x^k\| \ll N^{-\lambda-\epsilon}.$$

Next, by (4.2), (3.23), (3.29), (3.30)₁ we see that $1 \leq nqm_I = x \ll N^{\sigma_2}$, where

$$\begin{aligned} \sigma_2 &= (2\lambda + 2\epsilon(1 + R^{-1}) - \rho)g/(1 - \epsilon g) + (RKp + \epsilon) + (\lambda + \epsilon(1 + (2/R)) - \rho) \\ &= \rho(RK/s - g(k, R-1) - 1) + \lambda(2g(k, R-1) + 1) + B\epsilon \\ &< \lambda(2g(k, R-1) + 1) + B\epsilon, \end{aligned}$$

for some B depending on k, R only. Then by (3.19) and Lemma 5 ((2.13)), we have

$$(4.10) \quad \sigma_2 < \lambda(2g(k, R-1) + 1) + B\epsilon < 1 - \epsilon.$$

Hence

$$(4.11) \quad 1 \leq x \ll N^{1-\epsilon}.$$

(4.9) and (4.11) show that we have obtained an integer x satisfying

$$(4.12) \quad 1 \leq x \leq N \quad \text{and} \quad \max_{1 \leq i \leq R} (\|\theta_i x^k\|) \leq N^{-\lambda}.$$

This contradicts our supposition (3.1) since if we let $x_{j_0} = x$ (for j_0 see statement between (3.7) and (3.8)) and $x_j = 0$ for all $j \neq j_0$ then we have a particular vector $X = (x_1, \dots, x_j, \dots, x_s)$ for which

$$f_i(X) = \sum_{j=1}^s \theta_{ij} x_j^k = \theta_{ij_0} x_{j_0}^k = \theta_i x^k,$$

where $i = 1, \dots, R$; $R \geq 4$. So by (3.19) with a suitable choice of ϵ Theorem 1 is true for $R (\geq 4)$, if it is true for $R-1$.

It remains to see that Theorem 1 is true for $R=3$. For the case $R=3$ the proof follows exactly in the same way as that for $R \geq 4$ except that now Corollary 1 ((1.10)) is known for $R=2$ (a special case of Theorem L). This proves Theorem 1.
