RESULTS ON SUMS OF CONTINUED FRACTIONS

BY

JAMES L. HLAVKA

ABSTRACT. Let $F(m)$ be the (Cantor) set of infinite continued fractions with partial quotients no greater than m and let $F(m) + F(n) = \{a + \beta: a \in F(m), \beta \in F(n)\}$. We show that $F(3) + F(4)$ is an interval of length $1.14 \dots$ so every real number is the sum of an integer, an element of $F(3)$ and an element of $F(4)$. Similar results are given for $F(2) + F(7)$, $F(2) + F(2) + F(4)$, $F(2) + F(3) + F(3)$ and $F(2) + F(2) + F(2) + F(2)$. The techniques used are applicable to any Cantor sets in $\mathbb{R}$ for which certain parameters can be evaluated.

Marshall Hall, Jr. [3] proved that $F(4) + F(4) \equiv \mathbb{R} \pmod{1}$ (all notation is defined in the next paragraph) and posed the question: is $F(3) + F(4) \equiv \mathbb{R} \pmod{1}$? In this paper we prove $F(3) + F(4) \equiv \mathbb{R} \pmod{1}$ and several other results, summarized in Table 1. Only two questions concerning when a sum of $F(m_i) \equiv \mathbb{R}$ remain open: $F(2) + F(5) \equiv \mathbb{R}$? and $F(2) + F(6) \equiv \mathbb{R}$? We conjecture that they are both false.

$F(2) + F(4) \not\equiv \mathbb{R}$	$F(3) + F(3) \not\equiv \mathbb{R}$	$F(2) + F(2) + F(3) \not\equiv \mathbb{R}$
$F(2) + F(5) ?$	$F(3) + F(4) \equiv \mathbb{R}$	$F(2) + F(2) + F(4) \equiv \mathbb{R}$
$F(2) + F(6) ?$		$F(2) + F(3) + F(3) \equiv \mathbb{R}$
$F(2) + F(7) \equiv \mathbb{R}$		$F(2) + F(2) + F(2) + F(2) \equiv \mathbb{R}$

Table 1. All congruences are modulo 1

We let $\mathbb{N}$ be the natural numbers and $\mathbb{R}$ the real numbers. Lower case Roman letters except g and h will be elements of $\mathbb{N}$; Greek letters elements of $\mathbb{R}$. Let

$$\langle a_1, a_2, \dots \rangle = \frac{1}{a_1} + \frac{1}{a_2} + \dots,$$

$$\langle a_1, \dots, a_r, \overline{a_{r+1}, \dots, a_s} \rangle$$

$$= \langle a_1, \dots, a_r, a_{r+1}, \dots, a_s, a_{r+1}, \dots, a_s, \dots \rangle,$$

and

$$F(m) = \{\langle a_1, a_2, \dots \rangle : 1 \leq a_i \leq m \text{ for all } i \in \mathbb{N}\}.$$

When working with continued fractions it is convenient to write intervals without ordering their endpoints, so we define

$$(\alpha, \beta) = \{\xi \in \mathbb{R} : \min(\alpha, \beta) < \xi < \max(\alpha, \beta)\}$$

and

$$[\alpha, \beta] = \{\xi \in \mathbb{R} : \min(\alpha, \beta) \leq \xi \leq \max(\alpha, \beta)\}.$$

If A and B are subsets of $\mathbb{R}$, let $\bar{A}$ = the span of $A = \sup(\alpha - \beta)$ over all $\alpha, \beta \in A$ and $A + B = \{\alpha + \beta : \alpha \in A, \beta \in B\}$. Write " $A + B \equiv \mathbb{R} \pmod{1}$ " to mean " $\xi \in \mathbb{R}$ implies $\xi \equiv \alpha + \beta \pmod{1}$ for some $\alpha \in A, \beta \in B$." Let $P(m)$ be the special closed interval $[\langle \overline{m}, 1 \rangle, \langle 1, \overline{m} \rangle]$.

Note that $\langle \overline{m}, 1 \rangle$ and $\langle 1, \overline{m} \rangle$ are the least and greatest elements of $F(m)$, respectively, so $F(m) \subset P(m)$. Moreover $F(m) \subset F(m+1)$. The latter inclusion immediately shows that every question of the form $\sum_i F(m_i) \equiv \mathbb{R}$? is covered in Table 1.

$F(m)$ is a Cantor set so the natural approach to computing $\sum F(m_i)$ is by deleting intervals from the $P(m_i)$. Our objective is to devise an algorithm, called a construction of $F(m)$, which controls the order of these deletions sufficiently to establish that $\sum F(m_i) = \sum P(m_i)$ whenever this is true. (This is the same approach Hall used to investigate $F(4) + F(4)$.)

Lemma 1. $F(m) = P(m) \setminus O(m)$ = the set-theoretic difference of $P(m)$ and $O(m)$, where $O(m)$ is defined by

$$(1) \quad O(m) = \bigcup \{ \langle \langle a_1, \dots, a_s, \overline{1, m} \rangle, \langle a_1, \dots, a_s + 1, \overline{m, 1} \rangle \rangle : s \in \mathbb{N},$$

$$1 \leq a_i \leq m \text{ for } i \leq s \text{ and } a_s \neq m \}.$$

Proof. We show that $O(m)$ is composed of precisely those intervals which are deleted from $P(m)$ to form $F(m)$.

First assume $\alpha \in P(m) \setminus F(m)$. Then α has a first partial quotient a_{r+1} which is greater than m , with $r > 0$ and $a_r \neq 1$ when $r = 1$. Now if $a_r = 1$ then

$$\alpha = \langle a_1, \dots, a_{r-1}, a_r, \dots \rangle$$

$$\in \langle \langle a_1, \dots, a_{r-1} + 1, \overline{m, 1} \rangle, \langle a_1, \dots, a_{r-1}, \overline{1, m} \rangle \rangle$$

and if $a_r > 1$ then

$$\alpha \in (\langle a_1, \dots, a_r - 1, \overline{1, m} \rangle, \langle a_1, \dots, a_r, \overline{m, 1} \rangle),$$

so $\alpha \in O(m)$. Conversely if $\alpha \in (\langle a_1, \dots, a_s, \overline{1, m} \rangle, \langle a_1, \dots, a_s + 1, \overline{m, 1} \rangle) \subset O(m)$, then

$$(2) \alpha \in (\langle a_1, \dots, a_s, \overline{1, m} \rangle, \langle a_1, \dots, a_s + 1 \rangle),$$

$$(3) \alpha = \langle a_1, \dots, a_s + 1 \rangle, \text{ or}$$

$$(4) \alpha \in (\langle a_1, \dots, a_s + 1 \rangle, \langle a_1, \dots, a_s + 1, \overline{m, 1} \rangle).$$

If (2) then $\alpha = \langle a_1, \dots, a_s, \alpha' \rangle$ where $\overline{1, m} < \alpha' < 1$ so $\alpha' \notin F(m)$. Hence $\alpha \notin F(m)$. If (4) then $\alpha = \langle a_1, \dots, a_{s+1}, \alpha' \rangle$ where $\alpha' < \overline{m, 1}$ and again $\alpha \notin F(m)$. Lastly, (3) implies $\alpha \notin F(m)$ since $F(m)$ contains only infinite continued fractions. $\square$

We now define a construction of $F(m)$ as follows. Let $I_m^2 = P(m)$. Choose an interval O_m^2 of $O(m)$ and delete it from I_m^2 , leaving two new intervals I_m^3 and I_m^4 . From each delete an interval of $O(m)$, say O_m^3 and O_m^4 respectively. I_m^3 will be split into two intervals I_m^5 and I_m^6 ; I_m^4 will be split into I_m^7 and I_m^8 . From each of $I_m^5, \dots, I_m^8$ delete the interval $O_m^5, \dots, O_m^8$ respectively. Continue in this way. This procedure is demonstrated in Figures 1a and 1b. If $O(m) = \bigcup_{i=2}^{\infty} O_m^i$ we call this procedure a construction C of $F(m)$. We call $F_m^k = \bigcup_{j=2^{k-1}+1}^{2^k} I_m^j$ the k th step in the construction of $F(m)$.

Figure 1a

Figure 1b

Lemma 2. If C is any construction of $F(m)$, $m > 1$, and F_m^k is the k th step in this construction, then $F(m) = \bigcap_{k=1}^{\infty} F_m^k$.

Proof. Obvious from Figure 1b. $\square$

Definition. If C is a construction of $F(m)$, then

$$g_m = g_m(C) = \sup_i (\overline{O_m^i / I_m^i}),$$

$$h_m = h_m(C) = \inf_i \left(\inf_i (\overline{I_m^{2i-1} / I_m^i}), \inf_i (\overline{I_m^{2i} / I_m^i}) \right),$$

and

$$h'_m = h'_m(C) = \sup_i \left(\sup_i (\overline{I_m^{2i-1} / I_m^i}), \sup_i (\overline{I_m^{2i} / I_m^i}) \right).$$

Theorem 3. If there exist constructions C and C' of $F(m)$ and $F(n)$ respectively such that

$$(5) \quad g_m(C) \cdot g_n(C') \leq h_m(C) \cdot h_n(C') \text{ and}$$

$$(6) \quad g_m(C) \cdot \overline{P(m)} \leq \overline{P(n)} \text{ and } g_n(C') \cdot \overline{P(n)} \leq \overline{P(m)}$$

then $F(m) + F(n) = P(m) + P(n)$.

Proof. Let $\{I_m^i\}_{i=2}^{\infty}$ and $\{I'_n{}^j\}_{j=2}^{\infty}$ be the intervals appearing in the constructions C and C' respectively. Call the intervals I_m^i and $I'_n{}^j$ compatible (with respect to C and C'), written $I_m^i \sim I'_n{}^j$, iff

$$(7) \quad g_m \cdot \overline{I_m^i} \leq \overline{I'_n{}^j} \text{ and } g_n \cdot \overline{I'_n{}^j} \leq \overline{I_m^i}.$$

Call the intervals I_m^i and $I'_n{}^j$ M -dividable, written $I_m^i \overset{M}{\sim} I'_n{}^j$, iff (8) or (9) is true, where (8) and (9) are the following (symmetric) conditions.

$$(8.1) \quad I_m^{2i-1} \sim I'_n{}^j \text{ and } I_m^{2i} \sim I'_n{}^j,$$

$$(8) \quad (8.2) \quad (I_m^{2i-1} + I'_n{}^j) \cup (I_m^{2i} + I'_n{}^j) = I_m^i + I'_n{}^j, \text{ and}$$

$$(8.3) \quad M \cdot \overline{I'_n{}^j} \geq \overline{I_m^i}.$$

$$(9.1) \quad I_m^i \sim I'_n{}^{2j-1} \text{ and } I_m^i \sim I'_n{}^{2j},$$

$$(9) \quad (9.2) \quad (I_m^i + I'_n{}^{2j-1}) \cup (I_m^i + I'_n{}^{2j}) = I_m^i + I'_n{}^j, \text{ and}$$

$$(9.3) \quad M \cdot \overline{I'_n{}^j} \geq \overline{I_m^i}.$$

The four pairs of intervals appearing in (8.1) and (9.1) are said to be derived from the pair (I_m^i, I_n^j) .

It suffices to show that for some $M \in \mathbb{R}^+$, $I_m^i \sim I_n^j$ implies $I_m^i \overset{M}{\sim} I_n^j$ for all $i, j \geq 2$. To prove this, set $S_0 = \{(I_m^2, I_n^2)\}$ and

$$S_{r+1} = \{(I, J): I \sim J \text{ and } (I, J) \text{ is derived from a pair } (I_0, J_0) \in S_r\}.$$

Clearly

$$\bigcup \{I + J: (I, J) \in S_{r+1}\} = \bigcup \{I + J: (I, J) \in S_r\} = \dots = I_m^2 + I_n^2 = P(m) + P(n).$$

If $(I, J) \in S_r$, then $\bar{I} \cdot \bar{J} \leq \lambda^r \cdot \bar{I}_m^2 \cdot \bar{I}_n^2 \rightarrow 0$ as $r \rightarrow \infty$, where $\lambda = \max(1 - h_m, 1 - h_n) < 1$ (if h_m or $h_n = 0$ then g_m or $g_n = 0$ by (5) so $F(m)$ or $F(n)$ is not a Cantor set—contradiction). Since $I \sim J$, the ratio $\bar{I}/\bar{J}$ is bounded so $\bar{I} \rightarrow 0$ and $\bar{J} \rightarrow 0$. Therefore for each i there is an r_0 such that O_m^i has been deleted from every I appearing in a pair $(I, J) \in S_r$, $r > r_0$. Since $O(m) = \bigcup_{i=2}^{\infty} O_m^i$,

$$(10) \quad \alpha(m) \cap \left(\bigcap_{r=0}^{\infty} \left(\bigcup \{I: (I, J) \in S_r\} \right) \right) = \emptyset.$$

But for all r , $F(m) \subset \bigcup \{I: (I, J) \in S_r\} \subset P(m)$ so (10) and Lemma 1 yield

$$F(m) = \bigcap_{r=0}^{\infty} \left(\bigcup \{I: (I, J) \in S_r\} \right).$$

Similarly for $F(n)$. Since the sequence $\{\bigcup \{I: (I, J) \in S_r\}\}_{r=0}^{\infty}$ is a nested sequence of compact sets, we obtain directly the result

$$F(m) + F(n) = \bigcap_{r=0}^{\infty} \left(\bigcup \{I + J: (I, J) \in S_r\} \right) = \bigcap_{r=0}^{\infty} (P(m) + P(n)) = P(m) + P(n).$$

Now fix $M \geq \max(h_m/g_n, h_n/g_m)$ and assume $I_m^i \sim I_n^j$. Since $g_m g_n \leq h_m h_n$, we must have

$$(11) \quad \bar{I}_m^i / \bar{I}_n^j \geq g_n / h_m$$

or

$$(12) \quad \bar{I}_m^i / \bar{I}_n^j \leq h_n / g_m.$$

Assuming (11) we will verify (8). Similarly (9) will follow from (12), so this will show $I_m^i \overset{M}{\sim} I_n^j$. So assume (11) and set $k = 2i - 1$ or $2i$. Then recalling the definition of h_m ,

$$\overline{l_m^k} \geq h_m \cdot \overline{l_m^i} \geq g_n \cdot \overline{l_n^i} \quad \text{and} \quad \overline{l_n^j} \geq g_m \cdot \overline{l_m^i} \geq g_m \cdot \overline{l_m^k},$$

so $l_m^k \sim l_n^j$. To check (8.2), let $l_m^{2i-1} = [\alpha, \beta]$, $l_m^{2i} = [\gamma, \delta]$ and $l_n^j = [\alpha_0, \delta_0]$, with $\alpha < \beta < \gamma < \delta$ and $\alpha_0 < \delta_0$. Since

$$(13) \quad \overline{l_n^j} \geq g_m \cdot \overline{l_m^i} \geq \overline{O_m^i},$$

we have $\delta_0 - \alpha_0 \geq \gamma - \beta$ or $\beta + \delta_0 \geq \gamma + \alpha_0$. Then

$$\begin{aligned} (l_m^{2i-1} + l_n^j) \cup (l_m^{2i} + l_n^j) &= [\alpha + \alpha_0, \beta + \delta_0] \cup [\gamma + \alpha_0, \delta + \delta_0] \\ &= [\alpha + \alpha_0, \delta + \delta_0] = l_m^i + l_n^j. \end{aligned}$$

Lastly, (8.3) is satisfied by our choice of M . $\square$

Lemma 4. If $\alpha = \langle a_1, \dots, a_s, \alpha' \rangle$, $\beta = \langle a_1, \dots, a_s, \beta' \rangle$, $\alpha' > 0$, $\beta' > 0$, $\langle a_1, \dots, a_s \rangle = p_s/q_s$, $\langle a_1, \dots, a_{s-1} \rangle = p_{s-1}/q_{s-1}$ and $Q = q_{s-1}/q_s$, then

$$(\alpha' - \beta')/(\alpha - \beta) = (Q + \alpha')(Q + \beta')(-1)^{s+1} q_s^2.$$

Proof. We have

$$\begin{aligned} \alpha - \beta &= \frac{p_s \alpha' + p_{s-1}}{q_s \alpha' + q_{s-1}} - \frac{p_s \beta' + p_{s-1}}{q_s \beta' + q_{s-1}} \\ &= \frac{p_s}{q_s} \left\{ \frac{\alpha' + Q + p_{s-1}/p_s - Q}{\alpha' + q_{s-1}/q_s} - \frac{\beta' + Q + p_{s-1}/p_s - Q}{\beta' + q_{s-1}/q_s} \right\} \\ &= \frac{p_s}{q_s} \left(\frac{p_{s-1}}{p_s} - Q \right) \left\{ \frac{1}{\alpha' + Q} - \frac{1}{\beta' + Q} \right\} \\ &= \frac{(-1)^{s+1} (\alpha' - \beta')}{q_s^2 (\alpha' + Q)(\beta' + Q)}, \end{aligned}$$

since $p_{s-1}q_s - p_s q_{s-1} = (-1)^s$. The result follows immediately. $\square$

Lemma 5. If $\gamma = \langle a_1, \dots, a_s, \gamma' \rangle$, $\delta = \langle a_1, \dots, a_s, \delta' \rangle$, $\gamma' > 0$, $\delta' > 0$, and $\alpha, \beta, \alpha', \beta', Q$ are as in Lemma 4, then

$$(14) \quad \frac{\alpha - \beta}{\gamma - \delta} = \frac{\alpha' - \beta'}{\gamma' - \delta'} \cdot \frac{(Q + \gamma')(Q + \delta')}{(Q + \alpha')(Q + \beta')}$$

and $Q \in [1/(a_s + 1), 1]$.

Proof. Statement (14) is an immediate corollary of Lemma 4. The restriction on Q follows from the well-known result that $Q = \langle a_s, \dots, a_1 \rangle$. $\square$

Theorem 6. $F(3) + F(4) = P(3) + P(4) = [\langle \overline{3, 1} \rangle + \langle \overline{4, 1} \rangle, \langle \overline{1, 3} \rangle + \langle \overline{1, 4} \rangle] = [.4709\dots, 1.6197\dots]$.

Proof. We produce constructions of $F(3)$ and $F(4)$ satisfying the hypotheses of Theorem 3. Let us begin by defining a canonical construction, C_m , of $F(m)$ for any m , as follows. I_m^2 must be $[\overline{m, 1}, \overline{1, m}]$. If

$$I_m^i = [\langle a_1, \dots, a_s, j, \overline{m, 1} \rangle, \langle a_1, \dots, a_s, m, \overline{1, m} \rangle]$$

with $s \geq 0$ and $j \neq m$ then

$$O_m^i = (\langle a_1, \dots, a_s, j, \overline{1, m} \rangle, \langle a_1, \dots, a_s, j+1, \overline{m, 1} \rangle)$$

so that

$$I_m^{2i-1} = [\langle a_1, \dots, a_s, j, \overline{m, 1} \rangle, \langle a_1, \dots, a_s, j, \overline{1, m} \rangle]$$

and

$$I_m^{2i} = [\langle a_1, \dots, a_s, j+1, \overline{m, 1} \rangle, \langle a_1, \dots, a_s, m, \overline{1, m} \rangle].$$

It is relatively easy to show that $\bigcup_{i=2}^{\infty} O_m^i = O(m)$ so this does define a construction of $F(m)$. The value of the constructions C_m is that we can readily calculate $g_m(C_m)$ and $h_m(C_m)$ (and $h'_m(C_m)$, which will be needed later). We have

$$\begin{aligned} g_m(C_m) &= \max_{i \geq 2} (O_m^i / I_m^i) \\ &= \max \frac{\langle a_1, \dots, a_s, j, \overline{1, m} \rangle - \langle a_1, \dots, a_s, j+1, \overline{m, 1} \rangle}{\langle a_1, \dots, a_s, j, \overline{m, 1} \rangle - \langle a_1, \dots, a_s, m, \overline{1, m} \rangle} \end{aligned}$$

over $1 \leq j \leq m$, $s \geq 0$ and $1 \leq a_i \leq m$ for $i \leq s$. Using Lemma 5, we obtain

$$g_m(C_m) \leq \max \left\{ \frac{\langle j, \overline{1, m} \rangle - \langle j+1, \overline{m, 1} \rangle}{\langle j, \overline{m, 1} \rangle - \langle m, \overline{1, m} \rangle} \cdot \frac{(Q + \langle j, \overline{m, 1} \rangle)(Q + \langle m, \overline{1, m} \rangle)}{(Q + \langle j, \overline{1, m} \rangle)(Q + \langle j+1, \overline{m, 1} \rangle)} \right\}$$

over $1 \leq j \leq m$ and $Q \in [1/(m+1), 1]$. For each allowable value of j this expression is a rational function in Q whose maximum on the interval $[1/(m+1), 1]$ can be readily calculated. A Univac 1108 was used to perform these calculations and then maximize over j (and for similar calculations arising later). We thus obtain the bounds

$$g_3(C_3) \leq .2992\dots \quad \text{and} \quad g_4(C_4) \leq .2278\dots$$

Similarly

$$\begin{aligned}
h_m(C_m) &= \min_{i \geq 2} \left(\min \left(\overline{l_m^{2i-1}} / \overline{l_m^i}, \overline{l_m^{2i}} / \overline{l_m^i} \right) \right) \\
&= \min_{j, a_i} \left(\min \left(\frac{\langle a_1, \dots, a_s, j, \overline{1, m} \rangle - \langle a_1, \dots, a_s, j, \overline{m, 1} \rangle}{\langle a_1, \dots, a_s, m, \overline{1, m} \rangle - \langle a_1, \dots, a_s, j, \overline{m, 1} \rangle} \right. \right. \\
&\quad \left. \left. \frac{\langle a_1, \dots, a_s, m, \overline{1, m} \rangle - \langle a_1, \dots, a_s, j+1, \overline{m, 1} \rangle}{\langle a_1, \dots, a_s, m, \overline{1, m} \rangle - \langle a_1, \dots, a_s, j, \overline{m, 1} \rangle} \right) \right) \\
&\geq \min_{j, Q} \left(\min \left(\frac{\langle j, \overline{1, m} \rangle - \langle j, \overline{m, 1} \rangle}{\langle m, \overline{1, m} \rangle - \langle j, \overline{m, 1} \rangle} \cdot \frac{(Q + \langle m, \overline{1, m} \rangle)}{(Q + \langle j, \overline{1, m} \rangle)}, \right. \right. \\
&\quad \left. \left. \frac{\langle m, \overline{1, m} \rangle - \langle j+1, \overline{m, 1} \rangle}{\langle m, \overline{1, m} \rangle - \langle j, \overline{m, 1} \rangle} \cdot \frac{(Q + \langle j, \overline{m, 1} \rangle)}{(Q + \langle j+1, \overline{m, 1} \rangle)} \right) \right),
\end{aligned}$$

from which we obtain

$$h_3(C_3) \geq .2471\dots \quad \text{and} \quad h_4(C_4) \geq .2963\dots$$

A simple multiplication shows that

$$g_3(C_3) \cdot g_4(C_4) \leq .0667 < .0731 \leq h_3(C_3) \cdot h_4(C_4).$$

Also

$$g_3 \cdot \overline{P(3)} \leq .2992 \times .5276 < P(4) = .6212 \dots < \frac{.5276}{.2278} \leq \frac{\overline{P(3)}}{g_4}$$

so by Theorem 3 we have the result $F(3) + F(4) = P(3) + P(4)$. $\square$

Corollary 7. $F(3) + F(4) \equiv R \pmod{1}$.

Proof. This is obvious since $F(3) + F(4)$ contains an interval of length greater than one. $\square$

The values of g_3 , g_4 , h_3 and h_4 are in fact equal to the bounds given because these bounds arise from $Q = 1/(m+1)$ or $Q = 1$, which are possible values of Q . For g_2 and h_2 , below, this does not happen.

Applying Theorem 3 to the canonical constructions of $F(2)$ and $F(12)$ as above we can establish $F(2) + F(12) = P(2) + P(12)$, but now we find that the canonical construction of $F(12)$ is not an optimal construction in terms of minimizing the ratio g_{12}/h_{12} . This is because the maximal value of $\overline{O_m^i}/\overline{l_m^i}$ always occurs at $j = m-1$ but the minimal value of $\min(\overline{l_m^{2i-1}}, \overline{l_m^{2i}})/\overline{l_m^i}$

only occurs at $j = m - 1$ if $m \leq 4$. A noncanonical construction can allow us to lower the number 12, but the best result is obtained by extending Theorem 3.

Theorem 8. *If there exist constructions C and C' of $F(m)$ and $F(n)$ respectively, such that*

$$(15) \quad \overline{O_m^i} \cdot \overline{O_n^j} \leq \min(\overline{I_m^{2i-1}}, \overline{I_m^{2i}}) \cdot \min(\overline{I_n^{2j-1}}, \overline{I_n^{2j}}) \quad \text{for all } i, j \geq 2,$$

$$(16) \quad g_m \cdot \overline{P(m)} \leq \overline{P(n)} \text{ and } g_n \cdot \overline{P(n)} \leq \overline{P(m)},$$

and

$$(17) \quad \max(h'_m, h'_n) \cdot g_m g_n \leq h_m h_n,$$

then $F(m) + F(n) = P(m) + P(n)$.

Proof. Call the intervals I_m^i and I_n^j M -dividable* iff (8), (9) or

$$(18.1) \quad (I_m^{2i-1} + I_n^{2j-1}) \cup (I_m^{2i-1} + I_n^{2j}) \cup (I_m^{2i} + I_n^{2j-1}) \\ \cup (I_m^{2i} + I_n^{2j}) = I_m^i + I_n^j \text{ and}$$

(18)

$$(18.2) \quad I_m^{2i-1} \sim I_n^{2j-1}, I_m^{2i-1} \sim I_n^{2j}, I_m^{2i} \sim I_n^{2j-1}, \text{ and } I_m^{2i} \sim I_n^{2j}$$

holds. The proof now parallels the proof of Theorem 3; the only significant difference being to show that a compatible pair is M -dividable* when neither (11) nor (12) holds. So assume

$$(19) \quad h_n / g_m \leq \overline{I_m^i} / \overline{I_n^j} \leq g_n / h_m.$$

Let $I_m^{2i-1} = [\alpha, \beta]$, $I_m^{2i} = [\gamma, \delta]$, $I_n^{2j-1} = [\alpha_0, \beta_0]$, and $I_n^{2j} = [\gamma_0, \delta_0]$. From (15) we obtain

$$\overline{O_m^i} \leq \min(\overline{I_n^{2j-1}}, \overline{I_n^{2j}}) \quad \text{or} \quad \overline{O_n^j} \leq \min(\overline{I_m^{2i-1}}, \overline{I_m^{2i}});$$

assume for simplicity the latter. Then $\gamma_0 - \beta_0 \leq \min(\beta - \alpha, \delta - \gamma)$ so $\alpha + \gamma_0 \leq \beta + \beta_0$ and $\gamma + \gamma_0 \leq \delta + \beta_0$. Then the LHS of (18.1) is

$$[\alpha + \alpha_0, \beta + \beta_0] \cup [\alpha + \gamma_0, \beta + \delta_0] \cup [\gamma + \alpha_0, \delta + \beta_0] \cup [\gamma + \gamma_0, \delta + \delta_0] \\ = [\alpha + \alpha_0, \beta + \delta_0] \cup [\gamma + \alpha_0, \delta + \delta_0] = [\alpha + \alpha_0, \delta + \delta_0] = I_m^i + I_n^j.$$

For $k = 2i - 1$ or $2i$, $l = 2j - 1$ or $2j$, we have

$$\overline{I_m^k} \geq h_m \cdot \overline{I_m^i} \geq \frac{h_m h_n}{g_m} \cdot \overline{I_n^j} \geq \frac{h_m h_n}{g_m h'_n} \cdot \overline{I_n^l} \geq g_n \cdot \overline{I_n^l}$$

and similarly $\overline{l_n^l} \geq g_m \cdot \overline{l_m^k}$ so $\overline{l_m^k} \sim \overline{l_n^l}$. $\square$

Theorem 9. $F(2) + F(7) = P(2) + P(7) = [.4928\dots, 1.6195\dots] \equiv \mathbb{R} \pmod{1}$.

Proof. The canonical constructions can be used. We again apply Lemma 5 to obtain the bounds

$$g_2 \leq .4456\dots, \quad h_2 \geq .1686\dots, \quad h'_2 \leq .4589\dots, \quad g_7 \leq .1343\dots,$$

$$h_7 \geq .2906\dots, \quad h'_7 \leq .6359\dots, \quad \text{and} \quad \frac{\overline{O_7^j}}{\min(\overline{l_7^{2j-1}}, \overline{l_2^{2j}})} \leq .3594\dots$$

Since $\min(\overline{l_2^{2i-1}}, \overline{l_2^{2i}})/\overline{O_2^i} \geq h_2/g_2$, it is now easy to verify the hypotheses of Theorem 8. $\square$

For any constructions of $F(2)$ and $F(6)$, equation (15) fails whenever an interval of the type $(\langle a_1, \dots, a_s, 5, \overline{1, 6} \rangle, \langle a_1, \dots, a_s, 6, \overline{6, 1} \rangle)$ is deleted from $F(6)$. Thus, as (15) is intuitively a "best possible" condition in the sense that no weakening approximations were made, it is probable that $F(2) + F(6) \neq P(2) + P(6)$. Moreover, since (15) fails infinitely often, $F(2) + F(6)$ may possibly be a Cantor set.

The negative results $F(3) + F(3) \not\equiv \mathbb{R} \pmod{1}$ and $F(2) + F(4) \not\equiv \mathbb{R} \pmod{1}$ can be verified directly. $P(2) + P(4)$ has length less than one and $F(3) \subset [\overline{\langle 3, 1 \rangle}, \langle 3, \overline{3, 1} \rangle] \cup [\overline{\langle 2, 1, 3 \rangle}, \langle 1, \overline{3} \rangle]$ yields

$$F(3) + F(3) \subset [.5274\dots, .62178\dots] \cup [.62200\dots, 1.5826\dots].$$

We now look at sums of $F(m_1) + \dots + F(m_s)$ with $s > 2$.

Theorem 10. Let $C_1, \dots, C_s$ be constructions of $F(m_1), \dots, F(m_s)$ respectively (not necessarily canonical constructions). If

$$(20) \quad h_m \leq \overline{l_m^2} / \overline{l_n^2} \text{ for } m, n \in \{m_1, \dots, m_s\}, \text{ and}$$

$$(21) \quad g_m + h_m \leq \sum_{i=1}^s h_{m_i} \text{ for } m \in \{m_1, \dots, m_s\}$$

then $F(m_1) + \dots + F(m_s) = P(m_1) + \dots + P(m_s)$.

Proof. Again we mimic the proof of Theorem 3. Let $(\overline{l_{m_1}^{j_1}}, \dots, \overline{l_{m_s}^{j_s}})$ be compatible iff

$$(22) \quad h_{m_i} \cdot \overline{l_{m_k}^{j_k}} \leq \overline{l_{m_i}^{j_i}} \quad \text{for } 1 \leq i, k \leq s.$$

Call $(l_{m_1}^{j_1}, \dots, l_{m_s}^{j_s})$ dividable iff

$$(23) \quad (l_n^{2j-1} + (l_{m_1}^{j_1} + \dots + \widehat{l_n} + \dots + l_{m_s}^{j_s})) \cup (l_n^{2j} + (l_{m_1}^{j_1} + \dots + \widehat{l_n} + \dots + l_{m_s}^{j_s})) \\ = l_{m_1}^{j_1} + \dots + l_{m_s}^{j_s},$$

and $(l_{m_1}^{j_1}, \dots, l_n^{2j-1}, \dots, l_{m_s}^{j_s})$ and $(l_{m_1}^{j_1}, \dots, l_n^{2j}, \dots, l_{m_s}^{j_s})$ are compatible, where $\widehat{}$ means omission and n is such that

$$(24) \quad \overline{l_n^j} \geq \overline{l_{m_i}^{j_i}} \quad \text{for } 1 \leq i \leq s.$$

Hypothesis (20) says the beginning s -tuple $(l_{m_1}^2, \dots, l_{m_s}^2)$ is compatible, so the proof reduces to showing that every compatible s -tuple is dividable. Let

$k = 2j - 1$ or $2j$. Then $\overline{l_n^k} \geq h_n \cdot \overline{l_n^j} \geq h_n \cdot \overline{l_{m_i}^{j_i}}$ for $1 \leq i \leq s$, and the other combinations of subscripts occurring in (22) trivially produce correct inequalities, so $(l_{m_1}^{j_1}, \dots, l_n^k, \dots, l_{m_s}^{j_s})$ is compatible. From (21), we have

$$g_n \leq h_{m_1} + \dots + \widehat{h_n} + \dots + h_{m_s}$$

so that

$$\overline{l_{m_1}^{j_1}} + \dots + \widehat{\overline{l_n^j}} + \dots + \overline{l_{m_s}^{j_s}} \geq h_{m_1} \cdot \overline{l_n^j} + \dots + \widehat{h_n \cdot \overline{l_n^j}} + \dots + h_{m_s} \cdot \overline{l_n^j} \\ = (h_{m_1} + \dots + \widehat{h_n} + \dots + h_{m_s}) \cdot \overline{l_n^j} \geq g_n \cdot \overline{l_n^j} \geq \overline{O_n^j}.$$

This is the analog of equation (13) and is precisely the inequality needed to establish (23). $\square$

Theorem 11. *The following are all true.*

$$F(2) + F(2) + F(4) = P(2) + P(2) + P(4) \equiv \mathbf{R}(\text{mod } 1),$$

$$F(2) + F(3) + F(3) = P(2) + P(3) + P(3) \equiv \mathbf{R}(\text{mod } 1),$$

and

$$F(2) + F(2) + F(2) + F(2) = P(2) + P(2) + P(2) + P(2) \equiv \mathbf{R}(\text{mod } 1).$$

Proof. Apply Theorem 10 to the canonical constructions of $F(2)$, $F(3)$ and $F(4)$. $\square$

The final result listed in Table 1, $F(2) + F(2) + F(3) \not\equiv \mathbf{R}$, results from inspecting the first few subdivisions of $F(2)$ and $F(3)$.

T. W. Cusick and R. A. Lee [1], [2] have investigated $\Sigma_i S(m_i)$, where

$$S(m) = \{ \langle a_1, a_2, \dots \rangle : a_i \geq m \text{ for all } i \} \\ \cup \{ \langle a_1, \dots, a_s \rangle : a_i \geq m \text{ for } 1 \leq i \leq s, s \geq 1 \} \cup \{0\}.$$

They have shown [2] that

$$(25) \quad \sum_{i=1}^m S(m) = [0, 1].$$

Our Theorem 10 can be applied to $\Sigma_i S(m_i)$ in place of $\Sigma_i F(m_i)$, whereupon (25) follows as a relatively easy special case.

More generally, Theorems 3, 8 and 10 are applicable to any Cantor sets for which g_m , h_m and h'_m can be evaluated.
