BALAYAGE IN FOURIER TRANSFORMS: GENERAL RESULTS, PERTURBATION, AND BALAYAGE WITH SPARSE FREQUENCIES

BY

GEORGE S. SHAPIRO

ABSTRACT. Let Λ be a discrete subset of an LCA group and E a compact subset of the dual group. Balayage is said to be possible for (Λ, E) if the Fourier transform of each measure on G is equal on E to the Fourier transform of some measure supported by Λ . Following Beurling, we show that this condition is equivalent to the possibility of bounding certain functions with spectra in E by their bounds on Λ . We derive consequences of this equivalence, among them a necessary condition on Λ for balayage when E is compact and open (a condition analogous to a density condition Beurling and Landau gave for balayage in Euclidean spaces).

We show that if balayage is possible for (Λ, E) and if Λ' is close to Λ , then balayage is possible for (Λ', E) . Explicit bounds for the needed closeness in R and R^n are given.

Using these perturbation techniques, we give examples of perfect sets $E \subset R$ with the property that there are "arbitrarily sparse" sets Λ with balayage possible for (Λ, E) .

1. Introduction and definitions. Beurling [2], [3] initiated the study of what he called "balayage of measures in Fourier transforms" in the case of Euclidean spaces and, more especially, the real line where he made profound use of complex variable techniques. As he was aware, many of his more elementary observations extend to general locally compact abelian groups.

Throughout, G will denote a locally compact abelian group and Γ the dual group of G , both written additively. We write $M(G)$ for the convolution algebra of regular, finite complex Borel measures on G . If $\Lambda \subset G$ is closed, $M(\Lambda)$ denotes the subspace of measures supported on Λ . If $\mu \in M(G)$ we write $\hat{\mu}$ for the (inverse) Fourier transform of μ so that

$$\hat{\mu}(\gamma) = \int_G \langle \gamma, x \rangle d\mu(x) \text{ for } \gamma \in \Gamma.$$

Key words and phrases. Balayage in Fourier transforms, convolution, set of sampling, dual Banach spaces, surjective linear operator, density, uniformly discrete, relatively dense, compact open subgroup, sparse set, Dirichlet set, homogeneous perfect set.

DEFINITION 1.1. If $\Lambda \subset G$ is closed and $E \subset \Gamma$, then balayage is possible for the pair (Λ, E) if for every $\alpha \in M(G)$ there is some $\mu \in M(\Lambda)$ with $\hat{\alpha}(\gamma) = \hat{\mu}(\gamma)$ for all $\gamma \in E$.

We shall always assume that Λ is discrete and E is compact. Thus, for $\mu \in M(\Lambda)$ we have a series representation, $\hat{\mu}(\gamma) = \sum a_\lambda \langle \gamma, \lambda \rangle$, the sum being over Λ .

Some important examples of balayage are given in [2] where Beurling showed that if $\Lambda \subset R$ is uniformly discrete and $E \subset R$ is an interval then balayage is possible for (Λ, E) if and only if the lower density $D_-(\Lambda)$ satisfies

$$(1) \quad D_-(\Lambda) > (1/2\pi) \text{ meas } (E).$$

Here $D_-(\Lambda) = \lim_{r \rightarrow \infty} n(r)/r$ where $n(r)$ is the least number of points of Λ contained in any interval of length r and $\text{meas } (E)$ is the Lebesgue measure of E .

Landau [7], using L^2 -methods, showed that, quite generally, (1) is necessary for balayage and that a similar result holds in R^n .

In §2, we give a reformulation of the problem of balayage. The major result is Theorem 2.4 showing the equivalence of the problem of balayage with a certain sampling problem. This is inspired by a similar result of Beurling; however, we eliminate certain restrictions which he needed. We then apply this theorem in §3 to give an analogue of the necessity of condition (1) for balayage in the case where E is compact and open.

The remaining three sections explore and exploit perturbation results, that is, results which state that if balayage is possible for (Λ, E) and if Λ' is "close" to Λ (in senses to be made precise) then balayage is possible also for (Λ', E) .

§4 contains a perturbation result for general LCA groups. In §5, we give explicit bounds for the needed closeness of Λ and Λ' in R and R^n .

In §6, we study and construct perfect sets E in R , called BAS sets, having the property that there are "arbitrarily sparse" sets Λ with balayage possible for (Λ, E) . Here we use the techniques of §4, an estimate from §5 and a certain norm estimate. Using Theorem 6.4 we see that "thinness" *per se* does not imply the BAS property.

Some of our results are generalizations of Beurling's and much of our work was inspired by [2], which is, unfortunately, unpublished. Where relevant, we include remarks detailing the connections.

The original versions of some of the results here appeared in the author's dissertation [10]. The author wishes to thank his advisor, Professor L. Loomis for introducing him to the problem of balayage (and, indeed, to abstract analysis) and for his encouragement, and Professor G. Mackey for a helpful conversation. We also thank H. Landau for making available his personal, handwritten copy of [2].

We now introduce some notations and conventions.

We regard $L^1(G)$ as a subset (and an ideal) of $M(G)$. All integrals dx , $d\gamma$, etc. are with respect to the relevant Haar measure. Mention of relations

holding almost everywhere (a.e.) or locally a.e. refer to Haar measure.

The elements of $L^\infty(G)$ and $L^1(G)$ are equivalence classes of functions but will, as usual, be denoted f, g, h , etc. When we need to mention an element of such a class, we will denote it f_0, g_0, h_0 , etc.

δ_x is the unit point measure at x , so that $\hat{\delta}_x(\gamma) = \langle \gamma, x \rangle$ for $\gamma \in \Gamma$.

If S is a subset of the domain of a function φ , $\varphi|_S$ denotes the restriction of φ to S and $\|\varphi\|_S = \sup\{|\varphi(s)|: s \in S\}$. On the other hand, if V is a normed linear space, $\|\varphi\|_V$ denotes the norm of φ , regarded as an element of V . (These two conventions will not clash.)

2. A condition equivalent to balayage. To develop such a condition we need first to recall some facts about $B(E)$, the Banach algebra of restrictions to E of Fourier transforms of measures. $B(E) = \{\varphi: \varphi = \hat{\mu}|_E \text{ for some } \mu \in M(G)\}$. Because E is compact, $B(E) = A(E)$, the algebra of restrictions to E of Fourier transforms of integrable functions, with equality of norms so that, for $\varphi \in B(E)$,

$$\begin{aligned}\|\varphi\|_{B(E)} &= \inf\{\|\mu\|: \mu \in M(G) \text{ and } \hat{\mu}|_E = \varphi\} \\ &= \inf\{\|f\|_1: f \in L^1(G) \text{ and } \hat{f}|_E = \varphi\}.\end{aligned}$$

(See [8, p. 121].)

Let $\mathcal{G}(E) = \{f: f \in L^1(G) \text{ and } \hat{f}|_E = 0\}$. Then we may view $B(E)$ as isometrically isomorphic to the quotient algebra $L^1(G)/\mathcal{G}(E)$ (using $\hat{}$ for "transport des structures").

Define a linear operator $L: M(\Lambda) \rightarrow B(E)$ by $L\mu = \hat{\mu}|_E$. By the definition of the $B(E)$ -norm, $\|L\| \leq 1$. (Actually, $\|L\| = 1$ because $\|L\delta_\lambda\|_{B(E)} = 1$ for $\lambda \in \Lambda$.)

We pause now to make a general definition. Suppose that X and Y are Banach spaces and that $T: X \rightarrow Y$ is a surjective bounded linear operator. We set $K(T) =$ the infimum of constants K such that for all $y \in Y$ there is some $x \in X$ with $Tx = y$ and $\|x\| \leq K\|y\|$. By the open mapping theorem, $K(T) < \infty$. If T is not surjective, we set $K(T) = \infty$ and $1/K(T) = 0$.

In our situation, following Beurling, we set $K(\Lambda, E) = K(L)$. Thus balayage is possible for (Λ, E) if and only if $K(\Lambda, E) < \infty$. (Always, $K(\Lambda, E) \geq 1$.)

Our major step in reformulating the question of balayage is to compute the adjoint of L . First, we must identify certain dualities.

Since Λ is discrete, we may think of $M(\Lambda)$ as $l^1(\Lambda)$ (the space of absolutely summable functions on Λ). Then $M(\Lambda)^* \approx l^\infty(\Lambda)$ (the bounded complex functions on Λ) under the pairing $\langle \mu, \varphi \rangle = \int \varphi d\mu = \sum \varphi(\lambda)\mu(\{\lambda\})$. Since $B(E) \approx L^1(G)/\mathcal{G}(E)$ we have $B(E)^* \approx \mathcal{G}(E)^\perp \subset L^1(G)^* \approx L^\infty(G)$ where $\mathcal{G}(E)^\perp$ is the annihilator of $\mathcal{G}(E)$. More specifically, $g \in L^\infty(G)$ belongs to $\mathcal{G}(E)^\perp$ if and only if $\langle f, g \rangle = \int_G f(x)g(x)dx = 0$ for all $f \in \mathcal{G}(E)$. This is equivalent to requiring that $(g^*) * f = 0$ for all $f \in \mathcal{G}(E)$ where $g^*(x) = g(-x)$. Thus, the pairing between $g \in \mathcal{G}(E)^\perp$ and $\varphi \in B(E)$ is given by

$$(2) \quad \langle \varphi, g \rangle = \int_G g(x) f(x) dx \quad \text{for any } f \in L^1(G) \text{ with } \hat{f}|E = \varphi.$$

This duality is more or less well known. Now, we would like to extend (2) to read

$$\langle \varphi, g \rangle = \int_G g d\mu \quad \text{where } \mu \in M(G) \text{ and } \hat{\mu}|E = \varphi.$$

This raises the problem that various versions of g which are equal locally a.e. may give different values to $\int_G g d\mu$. The correct generalization of (2) is

THEOREM 2.1. *Suppose $\varphi \in B(E)$, $\mu \in M(G)$ and $\hat{\mu}|E = \varphi$. If $g \in \mathcal{G}(E)^\perp$, then there is a unique continuous (indeed, uniformly continuous) function g_0 in the L^∞ -equivalence class of g and, for this function g_0 ,*

$$\langle \varphi, g \rangle = \int_G g_0(x) d\mu(x).$$

Statements similar to (but apparently not identical to) Theorem 2.1 have appeared previously, for example [8, p. 120, especially Corollary 2].

We defer the proof while we present three lemmas.

LEMMA 2.1. *Suppose h_0 is a bounded Borel function on G , f_0 is (Haar)-integrable and $\mu \in M(G)$. Then*

$$(3) \quad h_0 * (\mu * f_0) = (h_0 * \mu) * f_0 \quad (\text{everywhere}).$$

PROOF. [4, pp. 726–728] shows that $h_0 * \mu$ is a Borel function on G so that the right-hand side of (3) is defined. The equation itself follows readily from Fubini's theorem and the translation invariance of Haar measure.

REMARK. The right-hand side of (3) is a bounded Borel function convolved with an integrable function and, therefore, depends only on the L^1 -equivalence class of f_0 . Likewise, the left-hand side depends only on the L^∞ -equivalence class of h_0 . Thus, if $h \in L^\infty$, $f \in L^1$ and $\mu \in M$, we may write $h * (\mu * f) = (h * \mu) * f$.

LEMMA 2.2. *Suppose $\mu \in M(G)$ satisfies $\hat{\mu}|E = 0$. If $g \in \mathcal{G}(E)^\perp$ and g_0 is a bounded Borel function in the L^∞ -equivalence class of g , then $(g_0^*) * \mu = 0$ locally a.e.*

PROOF. Suppose $f \in L^1(G)$. Then $\mu * f \in \mathcal{G}(E)$. Thus, $(g_0^*) * (\mu * f) = 0$. From Lemma 2.1, $((g^*) * \mu) * f = 0$ so that $(g_0^*) * \mu$ is a bounded Borel function which annihilates every L^1 -function and so must vanish locally a.e.

LEMMA 2.3. *If $g \in \mathcal{G}(E)^\perp$, then there is a (necessarily unique) uniformly continuous function g_0 in the L^∞ -equivalence class of g .*

PROOF. This is known: $\mathcal{G}(E)^\perp \subset L^\infty(G, E)$, those functions in $L^\infty(G)$ whose weak-* spectrum lies in E . Since E is compact, the result follows; see for example, [9, pp. 140–141].

Now we can prove Theorem 2.1. Under the hypotheses of that theorem, there is some $f \in L^1(G)$ with $\hat{f}|E = \varphi$. Then $(\mu - f)^\wedge|E = 0$, so, letting g_0 be the uniformly continuous version of g whose existence is guaranteed by Lemma 2.3 we have, by Lemma 2.2,

$$(4) \quad ((g_0^*) * (\mu - f))(x) = 0 \quad \text{locally a.e. in } x.$$

Now, $(g_0^*) * (\mu - f)$ is uniformly continuous (because g_0^* is so) (4) holds for all x . Setting $x = 0$ gives $((g_0^*) * \mu)(0) = ((g_0^*) * f)(0)$. Thus

$$\begin{aligned} \langle \varphi, g \rangle &= \int_G f g_0 dx = ((g_0^*) * f)(0) \\ &= ((g_0^*) * \mu)(0) = \int_G g_0 d\mu \end{aligned}$$

proving the theorem.

Henceforth, we shall view $\mathcal{G}(E)^\perp$ as a space of continuous functions on G , a view justified by Lemma 2.3.

THEOREM 2.2. *With L as defined above, $L^*: \mathcal{G}(E)^\perp \rightarrow l^\infty(\Lambda)$ is given by $L^*g = g|_\Lambda$.*

PROOF. Suppose $\mu \in M(\Lambda) \approx l^1(\Lambda)$. Then, $\langle \mu, L^*g \rangle = \langle L\mu, g \rangle = \langle \hat{\mu}|E, g \rangle = \int_G g d\mu = \sum g(\lambda)\mu(\{\lambda\}) = \langle \mu, g|_\Lambda \rangle$. Since this holds for all $\mu \in M(\Lambda)$, we have $L^*g = g|_\Lambda$.

We will need a functional-analytic result (used, for example, in the study of Helson sets). We rephrase Theorem E9 (of Appendix E) of [4] for our purposes.

THEOREM 2.3. *Suppose $L: X \rightarrow Y$ (where X and Y are Banach spaces) is a bounded linear operator with adjoint $L^*: Y^* \rightarrow X^*$. Suppose $C > 0$. Then the two following conditions are equivalent:*

1. L is surjective and $C = K(L)$.
2. $C\|L^*y^*\| \geq \|y^*\|$ for all $y^* \in Y^*$.

We apply this theorem to our $L: M(\Lambda) \rightarrow B(E)$. Define

$$k'(\Lambda, E) = \sup\{\|g\|_G / \|g\|_\Lambda : g \in \mathcal{G}(E)^\perp \text{ and } g \neq 0\}.$$

(This may be ∞ .) Applying Theorem 2.3 to L gives immediately

THEOREM 2.4. $K(\Lambda, E) = k'(\Lambda, E)$.

In particular, in order for balayage to be possible for (Λ, E) , each nonzero $g \in \mathcal{G}(E)^\perp$ must satisfy $g|_\Lambda \neq 0$. (Then Λ is said to be a set of sampling for $\mathcal{G}(E)^\perp$.)

REMARK. Beurling used the open mapping theorem to show the finiteness of $K(\Lambda, E)$ when balayage is possible. In place of $\mathcal{G}(E)^\perp$, however, he considered $C(G, E)$, the space of bounded continuous functions with spectra in E . He defined $k(\Lambda, E)$ in the same manner as our k' but using a sup over $C(G, E)$.

instead of $\mathcal{G}(E)^\perp$, and showed that if E satisfies his conditions (α) and (β) then $K(\Lambda, E) = k(\Lambda, E)$. Condition (α) is that every neighborhood, in E , of every point of E support a measure whose Fourier transform vanishes at infinity. Condition (β) is that E be a set of spectral synthesis, i.e., that $C(G, E) = \mathcal{G}(E)^\perp$. Thus, Theorem 2.4 contains Beurling's result. Note that, in general, $\mathcal{G}(E)^\perp \subset C(G, E)$ so that $k'(\Lambda, E) \leq k(\Lambda, E)$.

3. The case of compact, open E . We now give an application of Theorem 2.4 to the situation where E is a compact and open subset of Γ . We note that in the important case of totally disconnected groups, every compact subset can be approximated (from outside) by compact, open sets. We also remark that, for the groups of p -adic numbers, balayage and related matters where (in our notation) E is discrete and Λ is compact have been studied by various French workers. (See [8, p. 162ff.] and the references given in that book.)

Since E is compact and open, we may write $E = \bigcup_1^n (\gamma_k + H)$ where H is a compact and open subgroup of Γ and the various cosets $\gamma_k + H$, $k = 1, 2, \dots, n$, are distinct. (Apply, for example, [4, Theorem 7.5].)

We write $H^\perp$ for the annihilator of H , that is, $H^\perp = \{x \in G: \langle \gamma, x \rangle = 1 \text{ for all } \gamma \in H\}$. $H^\perp$ is a compact, open subgroup of G . We assume that the Haar measures m_G and m_Γ on G and Γ respectively are so normalized that the Fourier inversion theorem holds. In particular, we have $m_\Gamma(H)m_G(H^\perp) = 1$.

THEOREM 3.1. *With notation as above, if balayage is possible for (Λ, E) then Λ contains at least n elements from every coset of $H^\perp$.*

PROOF. We prove the contrapositive. Suppose that there is some x such that $\Lambda \cap (x + H^\perp) = \{\lambda_1, \lambda_2, \dots, \lambda_m\}$ and $m < n$. Then there is a nontrivial solution $(d_1, d_2, \dots, d_n)$ to the system of m equations in n unknowns:

$$\sum_{k=1}^n d_k \langle \gamma_k, \lambda_j \rangle = 0; \quad j = 1, 2, \dots, m.$$

Fixing one such solution, we define g by

$$g(t) = \begin{cases} \sum_1^n d_k \langle \gamma_k, t \rangle & \text{if } t \in x + H^\perp, \\ 0 & \text{if } t \notin x + H^\perp. \end{cases}$$

$\int_G |g|^2 = m_G(H^\perp) \sum |d_k|^2 \neq 0$ so g does not vanish identically. On the other hand, $g(\lambda_j) = 0$ for $j = 1, 2, \dots, m$ so that $g|_\Lambda = 0$. If we can show that $g \in \mathcal{G}(E)^\perp$, we will thus be able to conclude that $k'(\Lambda, E) = \infty$, proving the theorem. First we note that g is continuous since $x + H^\perp$ is open. Next, we look at $\check{g}(\gamma) = \hat{g}(-\gamma)$.

$$\begin{aligned} \check{g}(\gamma) &= \sum d_k \int_{x+H^\perp} \langle \gamma_k - \gamma, t \rangle dt \\ &= \sum d_k \langle \gamma_k - \gamma, x \rangle \int_{H^\perp} \langle \gamma_k - \gamma, t \rangle dt. \end{aligned}$$

Now, $\int_{H^\perp} \langle \gamma_k - \gamma, t \rangle dt$ can be nonzero only if $\gamma_k - \gamma$ is the trivial character on $H^\perp$, that is, only if $\gamma \in \gamma_k + H$. Thus, $\hat{g}$ vanishes off E . In particular, $g = (g^\sim)^\wedge$ which justifies our concluding that if $f \in \mathcal{G}(E)$, then $\int_G fg = \int_G f(g^\sim)^\wedge = \int_\Gamma \hat{f}\hat{g} = 0$ because $\hat{f}$ vanishes on E . Thus, $g \in \mathcal{G}(E)^\perp$, proving the theorem.

REMARK. Suppose we define

$$\Delta_-(\Lambda) = \liminf \frac{\#(\Lambda \cap K_j)}{m_G(K_j)}$$

where each K_j is the union of (finitely many) cosets of $H^\perp$, the K_j 's increase to G and $\#(S)$ is the number of elements in S . Δ_- is a not very intrinsic density analogous to D_- . If K_j is the union of m_j cosets of $H^\perp$, then $m_G(K_j) = m_j m_G(H^\perp)$ and, for balayage to be possible, we must have $\#(\Lambda \cap K_j) \geq m_j n$ for all j . In this case, $\Delta_-(\Lambda) \geq m_j n / m_j m_G(H^\perp) = nm_\Gamma(H) = m_\Gamma(E)$, a relation formally analogous to (1). (Here, unlike (1), we cannot require strict inequality, see Theorem 3.2.)

Because of algebraic complications, the converse to Theorem 3.1 is false unless $n = 1$, as the following example shows. Let $\Gamma (\approx G)$ be a *finite* group with a proper, nontrivial subgroup K . Let $\gamma_0 \in K$ be nonzero, let $H = \{0\}$ and let $E = \{0, \gamma_0\} = H \cup (\gamma_0 + H)$, so that $n = 2$. Let x_0 be a nonzero element of $K^\perp$ and let $\Lambda = \{0, x_0\}$. Λ meets each coset (there's only one) of $H^\perp = G$ twice. Let $f(t) = 1 - \langle -\gamma_0, t \rangle$. A simple computation shows that $\hat{f}(\gamma) = 0$ unless $\gamma \in E$ so one verifies readily that $f \in \mathcal{G}(E)^\perp$. However, f is nontrivial and $f|_\Lambda = 0$ because $\langle -\gamma_0, x_0 \rangle = 1$. Thus $k'(\Lambda, E) = \infty$. Such examples can be lifted to infinite LCA groups having two proper, compact and open subgroups.

We do have, however

THEOREM 3.2. *If H is a compact, open subgroup of Γ then balayage is possible for (Λ, H) if and only if Λ meets every coset of $H^\perp$.*

PROOF. The "only if" follows from Theorem 3.1. Let

$$h(t) = \begin{cases} m_\Gamma(H) & \text{if } t \in H^\perp, \\ 0 & \text{if } t \notin H^\perp. \end{cases}$$

One verifies easily that $\hat{h}$ is the characteristic function of H . If $g \in \mathcal{G}(H)^\perp$, Lemma 2.2 insures that $(g^*) * (\delta_0 - h) = 0$ so that

$$g(x) = \int_{H^\perp} g(x - t) m_\Gamma(H) dt.$$

Thus g is constant on the cosets of $H^\perp$. If Λ meets each coset of $H^\perp$ then $\|g\|_G = \|g\|_\Lambda$. Thus, $k'(\Lambda, H) = 1$, proving the theorem.

REMARK. A more general result of this kind, where H need not be compact, can be proved using a measurable choice argument [10, Theorem 5.2].

4. General perturbation results. For the purpose of comparing different discrete sets, we change our viewpoint slightly from that of §2. Let $\Lambda = \{\lambda_i\}_{i \in I}$ where the indexing puts Λ into one-to-one correspondence with the index set I . Since Λ is discrete, there is an isometry between $l^1(I)$ and $M(\Lambda)$ which makes the function $\alpha \in l^1(I)$ correspond to the measure $\sum \alpha(i)\delta_{\lambda_i}$.

Define $T_\Lambda: l^1(I) \rightarrow B(E)$ by $T_\Lambda \alpha = (\sum \alpha(i)\delta_{\lambda_i})^\wedge | E$. More explicitly,

$$(T_\Lambda \alpha)(\gamma) = \sum \alpha(i) \langle \gamma, \lambda_i \rangle \quad \text{for } \gamma \in E.$$

T_Λ is a bounded linear operator of norm 1 and balayage is possible for (Λ, E) if and only if T_Λ is surjective. Indeed, we easily see that $K(\Lambda, E) = K(T_\Lambda)$, in the notation of §2.

We shall use the following well-known result, one of whose proofs follows from the obvious iterative scheme. (See [1, Theorem 1.2] or [10, Proposition 4.1].) The idea of this result has also been used by Beurling to solve a related interpolation problem.

THEOREM 4.1. *Suppose X and Y are Banach spaces and S and T are bounded linear operators from X to Y . Then,*

$$|1/K(S) - 1/K(T)| \leq \|S - T\|.$$

In particular, if T is surjective and $\|S - T\| < 1/K(T)$, then S is surjective.

Suppose now that Λ' is another closed, discrete set in G and for each $i \in I$ we have an element $\lambda'_i \in \Lambda'$. Here (unlike the case for Λ) we do *not* assume that the λ'_i are distinct or that $\{\lambda'_i\}_{i \in I}$ is all of Λ' .

Define $S_{\Lambda'}: l^1(I) \rightarrow B(E)$ by $S_{\Lambda'} \alpha = (\sum \alpha(i)\delta_{\lambda'_i})^\wedge | E$. As above, if $S_{\Lambda'}$ is surjective, then balayage is possible for (Λ', E) . Because of the lack of assumptions on the indexing of the λ'_i we have only $K(\Lambda', E) \leq K(S_{\Lambda'})$.

To apply Theorem 4.1, we need an estimate of $\|T_\Lambda - S_{\Lambda'}\|$. If $x \in G$, we write $\langle \cdot, x \rangle$ for the function $\gamma \mapsto \langle \gamma, x \rangle$. (If we denoted this function by x , $x + y$ would have a double meaning.)

LEMMA 4.1.

$$\|T_\Lambda - S_{\Lambda'}\| \leq \sup\{\|1 - \langle \cdot, \lambda'_i - \lambda_i \rangle\|_{B(E)} : i \in I\}.$$

PROOF. Given $\alpha \in l^1(I)$ and $\gamma \in E$ we have

$$\begin{aligned} (T_\Lambda \alpha - S_{\Lambda'} \alpha)(\gamma) &= \sum \alpha(i) (\langle \gamma, \lambda_i \rangle - \langle \gamma, \lambda'_i \rangle) \\ &= \sum \alpha(i) \langle \gamma, \lambda_i \rangle (1 - \langle \gamma, \lambda'_i - \lambda_i \rangle). \end{aligned}$$

Now $\|\langle \cdot, \lambda_i \rangle\|_{B(E)} = 1$ and $B(E)$ is a normed algebra, so

$$\begin{aligned} \|T_\Lambda \alpha - S_{\Lambda'} \alpha\|_{B(E)} &\leq \sum |\alpha(i)| \|1 - \langle \cdot, \lambda'_i - \lambda_i \rangle\|_{B(E)} \\ &\leq \|\alpha\|_{l^1(I)} \sup\{\|1 - \langle \cdot, \lambda'_i - \lambda_i \rangle\|_{B(E)} : i \in I\}, \end{aligned}$$

from which the lemma follows.

LEMMA 4.2. *Given a compact set $E \subset \Gamma$, and $\varepsilon > 0$, there is a neighborhood U of 0 in G such that*

$$\sup\{\|1 - \langle \cdot, x \rangle\|_{B(E)} : x \in U\} < \varepsilon.$$

PROOF. Since E is compact, there is some $f \in L^1(G)$ with $\hat{f}|_E = 1$. We recall that $\lim_{x \rightarrow 0} \|f - f_x\|_1 = 0$, where $f_x(t) = f(t + x)$. There is, thus, a neighborhood U of 0 such that $\sup\{\|f - f_x\|_1 : x \in U\} < \varepsilon$. Now $\hat{f}_x(\gamma) = \langle \gamma, x \rangle \hat{f}(\gamma) = \langle \gamma, x \rangle$ for $\gamma \in E$. Thus, $(f - f_x)^\wedge = 1 - \langle \cdot, x \rangle$ on E so that $\|1 - \langle \cdot, x \rangle\|_{B(E)} \leq \|f - f_x\|_1$ and the lemma follows.

THEOREM 4.2. *Suppose balayage is possible for (Λ, E) . Then there is a neighborhood U of 0 in G with the following property: if Λ' is any discrete set such that for every $\lambda \in \Lambda$ there is some $\lambda' \in \Lambda'$ with $\lambda' - \lambda \in U$, then balayage is possible for (Λ', E) .*

PROOF. Let U be as in Lemma 4.2 with $\varepsilon = 1/K(\Lambda, E)$. Given Λ' as in the statement of the theorem, it is clear that Λ and Λ' may be indexed as in the discussion above. Then, by Lemma 4.1, $\|T_\Lambda - S_{\Lambda'}\| < 1/K(\Lambda, E) = 1/K(T_\Lambda)$ so, by Theorem 4.1, $S_{\Lambda'}$ is surjective and balayage is possible for (Λ', E) .

One would like to have U as large as possible. To this end, we need a good estimate of $\|1 - \langle \cdot, x \rangle\|_{B(E)}$. We take up this problem for Euclidean spaces next.

5. The Euclidean case. We deal first with $G = \mathbb{R}$, the real line, so that $\Gamma \approx \mathbb{R}$ also under the pairing $\langle \gamma, x \rangle = \exp(i\gamma x)$.

We note that if $E \subset F$ and $\varphi \in B(F)$ then $\varphi|_E \in B(E)$ and $\|\varphi|_E\|_{B(E)} \leq \|\varphi\|_{B(F)}$. We shall exploit this remark by considering intervals containing E .

We quote a result which we shall need again in §6. This appears in a different form and context on pp. 107 and 108 of [8].

LEMMA 5.1. *Suppose $b > 0$ and $|x|b < \pi$. Define*

$$z_k = \frac{x}{2} - \left(\frac{2k+1}{2b}\right)\pi \quad \text{for } k = 0, \pm 1, \pm 2, \dots$$

Then there is a measure $\mu = \sum c_k \delta_{z_k}$ such that

$$\|\mu\| = \sum |c_k| = 2 \sin(|x|b/2) \quad \text{and}$$

$$\hat{\mu}(\gamma) = 1 - \exp(i\gamma x) \quad \text{for } |\gamma| \leq b.$$

To make our formulas simpler, we define

$$s(t) = \begin{cases} 2 \sin(|t|/2) & \text{if } |t| \leq \pi, \\ 2 & \text{if } |t| \geq \pi. \end{cases}$$

LEMMA 5.2. $\|1 - \langle \cdot, x \rangle\|_{B([-b, b])} = s(xb)$.

PROOF. $s(xb) = \|1 - \langle \cdot, x \rangle\|_{[-b, b]} \leq \|1 - \langle \cdot, x \rangle\|_{B([-b, b])}$. The result of Lemma 5.1 and the observation that $\|1 - \langle \cdot, x \rangle\|_B \leq \|1\|_B + \|\langle \cdot, x \rangle\|_B = 2$ complete the proof.

THEOREM 5.1. Suppose balayage is possible for (Λ, E) . Let $2b = \text{diameter}(E)$ and suppose $a > 0$ is such that $s(ab) < 1/K(\Lambda, E)$.

Then, if Λ' is a discrete set such that for every $\lambda \in \Lambda$ there is some $\lambda' \in \Lambda'$ with $|\lambda' - \lambda| \leq a$, it follows that balayage is possible for (Λ', E) and that

$$1/K(\Lambda, E) - 1/K(\Lambda', E) \leq s(ab).$$

PROOF. Balayage is possible for (Λ, E) if and only if balayage is possible for $(\Lambda, E + \gamma)$. Thus, we may assume that $E \subset [-b, b]$. Let $U = [-a, a]$. Lemma 3.2 gives

$$\begin{aligned} \sup\{\|1 - \langle \cdot, x \rangle\|_{B(E)} : x \in U\} \\ \leq \sup\{\|1 - \langle \cdot, x \rangle\|_{B([-b, b])} : x \in U\} \\ = s(ab) < 1/K(\Lambda, E). \end{aligned}$$

Arguing as in Theorem 4.2, we obtain the result. The inequality follows from Theorem 4.1 and the fact that $K(\Lambda', E) \leq K(S_{\Lambda'})$.

REMARK. Beurling proved a similar result with $s(ab)$ replaced by $ab > s(ab)$. He worked with $C(R, E)$ and assumed his conditions (α) and (β) . Actually, his proof, which makes use of Bernstein's inequality, carries over verbatim to $\mathcal{G}(E)^\perp$ without these conditions. We need the present technique, however, to deal with more general groups and, in §6, with a different type of perturbation. Our proof of Lemma 6.1 is an adaptation and illustration of Beurling's argument.

We now consider the case where $G = R^n$ so $\Gamma = R^n$ also. We adopt the notation $\mathbf{x} = (x_1, x_2, \dots, x_n)$ and $\gamma = (\gamma_1, \gamma_2, \dots, \gamma_n)$ for elements of G and Γ respectively so that $\langle \gamma, \mathbf{x} \rangle = \exp(i \sum \gamma_k x_k) = \exp(i\gamma \cdot \mathbf{x})$. If $\mathbf{b} = (b_1, b_2, \dots, b_n)$ has nonnegative entries then we set

$$I(\mathbf{b}) = \{\gamma : |\gamma_k| \leq b_k \text{ for } k = 1, 2, \dots, n\}.$$

LEMMA 5.3. $\|1 - \langle \cdot, x \rangle\|_{B(I(\mathbf{b}))} \leq \sum_1^n s(x_k b_k)$.

PROOF. For $k = 1, 2, \dots, n$ we define a measure μ_k as follows:

If $|x_k|b_k < \pi$ we let μ be the measure on R constructed as in Lemma 5.1 with b replaced by b_k and x by x_k .

If $|x_k|b_k \geq \pi$ we let $\mu = \delta_0 - \delta_{x_k}$.

μ_k is then defined by the requirement that

$$\int_{R^n} f(v) d\mu_k(v) = \int_R f(0, \dots, 0, v_k, 0, \dots, 0) d\mu(v_k)$$

for reasonable (say bounded and continuous) functions f . Thus, $\hat{\mu}_k(\gamma) = 1 - \exp(i\gamma_k x_k)$ if $|\gamma_k| \leq b_k$ and $\|\mu_k\| = \|\mu\| = s(x_k b_k)$. Thus, in the special case where $\mathbf{x} = (0, \dots, 0, x_k, 0, \dots, 0)$, we have shown that $\|1 - \langle \cdot, \mathbf{x} \rangle\|_{B(I(\mathbf{b}))} \leq s(x_k b_k)$.

Now, let $\mathbf{x} = (x_1, x_2, \dots, x_n)$ and set $\mathbf{v}_1 = \mathbf{0}$ and $\mathbf{v}_k = (x_1, x_2, \dots, x_{k-1}, 0, \dots, 0)$ for $k = 2, 3, \dots, n$ and set $\mathbf{w}_k = (0, \dots, 0, x_k, 0, \dots, 0)$. Then

$$1 - \langle \gamma, \mathbf{x} \rangle = \sum_1^n \langle \gamma, \mathbf{v}_k \rangle (1 - \langle \gamma, \mathbf{w}_k \rangle).$$

$\|\langle \cdot, \mathbf{v}_k \rangle\|_B = 1$ and the $\mathbf{w}_k$ are of the special form for which we already have our estimate. Thus

$$\|1 - \langle \cdot, \mathbf{x} \rangle\|_{B(I(\mathbf{b}))} \leq \sum \|1 - \langle \cdot, \mathbf{w}_k \rangle\|_{B(I(\mathbf{b}))} \leq \sum s(x_k b_k).$$

REMARK. In the case where $\Gamma = \Gamma_1 \times \Gamma_2 \times \dots \times \Gamma_n$, the same idea would allow us to estimate $\|1 - \langle \cdot, \mathbf{x} \rangle\|_{B(E)}$ where $E = E_1 \times E_2 \times \dots \times E_n$, if we had estimates for each $\|1 - \langle \cdot, x_k \rangle\|_{B(E_k)}$.

THEOREM 5.2. Suppose balayage is possible for (Λ, E) where E (or some translate of E) $\subset I(\mathbf{b})$. Suppose $\mathbf{a}$ has positive entries and

$$\sum s(a_k b_k) < 1/K(\Lambda, E)$$

(which is certainly the case if $\mathbf{a} \cdot \mathbf{b} < 1/K(\Lambda, E)$).

If Λ' is a discrete set such that for every $\lambda \in \Lambda$ there is some $\lambda' \in \Lambda'$ with $\lambda' - \lambda \in I(\mathbf{a})$, then balayage is possible for (Λ', E) and

$$\frac{1}{K(\Lambda, E)} - \frac{1}{K(\Lambda', E)} \leq \sum s(a_k b_k).$$

PROOF. This follows from Lemma 5.3 exactly as Theorem 5.1 follows from Lemma 5.2.

6. Balayage with sparse sets of frequencies. Beurling's work on balayage dealt with the case where Λ has positive density. In this section, we go to the opposite extreme. We confine ourselves to the case $G = R$.

DEFINITION 6.1. E is called a BAS set (for balayage with arbitrarily sparse frequencies) if the following condition holds:

Given any sequence $h_1, h_2, \dots$ of real-valued functions, h_n having $n - 1$ real arguments (so that h_1 is a constant) there is a closed, discrete set $\Lambda = \{\lambda_n\}_1^\infty$ with $\lambda_n \geq h_n(\lambda_1, \lambda_2, \dots, \lambda_{n-1})$ for all n and with balayage possible for (Λ, E) .

We adapt our previous techniques to prove

THEOREM 6.1. *Suppose E is compact and there is a number $\delta < 1$ such that for every M there is a $t \geq M$ with $\|1 - \langle \cdot, t \rangle\|_{B(E)} \leq \delta$. Then E is a BAS set. (We could write our condition as $\liminf_{t \rightarrow \infty} \|1 - \langle \cdot, t \rangle\|_{B(E)} < 1$.)*

Before we prove this theorem, we need to know that if E is a compact set then there is a discrete set S with $K(S, E)$ arbitrarily close to 1. We give a proof of this fact using the method (referred to after Theorem 5.1) which Beurling used to study perturbation.

LEMMA 6.1. *Let Z denote the integers. If $a > 0$, $b > 0$, and $ab < 2$, then*

$$K(aZ, [-b, b]) \leq (1 - \frac{1}{2}ab)^{-1}.$$

PROOF. We prove the result for k' . Suppose that $\varphi \in \mathcal{G}([-b, b])^\perp$. Then the spectrum of φ lies in $[-b, b]$ so, by Bernstein's inequality (for derivatives of entire functions of exponential type)

$$|\varphi(x) - \varphi(x')| \leq b|x - x'| \|\varphi\|_R$$

for any $x, x' \in R$. (See, for example, [8, p. 149].)

Now, given $x \in R$ there is some $\lambda \in aZ$ with $|x - \lambda| \leq a/2$. Thus, $|\varphi(x) - \varphi(\lambda)| \leq b(a/2) \|\varphi\|_R$ whence $|\varphi(x)| \leq |\varphi(\lambda)| + (ab/2) \|\varphi\|_R$ and it follows that $\|\varphi\|_R(1 - ab/2) \leq \|\varphi\|_{aZ}$ so that

$$k'(aZ, [-b, b]) = \sup\{\|\varphi\|_R / \|\varphi\|_{aZ}\} \leq (1 - ab/2)^{-1}.$$

REMARK. This result is not sharp because (by (1)) $K(aZ, [-b, b]) < \infty$ if $ab < \pi$.

We now prove Theorem 6.1. For some b , $E \subset [-b, b]$. Pick a such that $\delta < 1 - ab/2$. Enumerate aZ as a sequence, $aZ = \{x_n\}_1^\infty$. Let functions h_n as in Definition 6.1 be given.

Proceeding inductively, by the hypothesis on E there is, at each step, some $t_n \geq h_n(\lambda_1, \lambda_2, \dots, \lambda_{n-1}) - x_n$ with $\|1 - \langle \cdot, t_n \rangle\|_{B(E)} \leq \delta$. Set $\lambda_n = t_n + x_n$; by increasing the t_n if necessary we may insure that the λ_n are distinct and that $\Lambda = \{\lambda_n\}$ is discrete.

By Lemmas 4.1 and 6.1,

$$\begin{aligned} \|T_\Lambda - T_{aZ}\| &\leq \sup\{\|1 - \langle \cdot, \lambda_n - x_n \rangle\|_{B(E)}\} \\ &= \sup\{\|1 - \langle \cdot, t_n \rangle\|_{B(E)}\} \leq \delta < 1 - ab/2 \\ &\leq 1/K(aZ, [-b, b]) \leq 1/K(aZ, E) = 1/K(T_{aZ}). \end{aligned}$$

Since T_{aZ} is surjective, Theorem 4.1 implies that T_Λ is surjective and our theorem follows.

REMARK. We have $K(\Lambda, E) \leq (1 - \delta - ab/2)^{-1}$ so we can make $K(\Lambda, E) < (1 - \delta)^{-1} + \varepsilon$ for any $\varepsilon > 0$.

We recall that E is called a Dirichlet set if there is a sequence t_n

$\rightarrow \infty$ with $\|1 - \langle \cdot, t_n \rangle\|_E \rightarrow 0$. E is called a Helson set if $B(E) = C(E)$, the algebra of all continuous complex functions on E . We shall see shortly that every Dirichlet set is a BAS set and that there are BAS sets which are neither Dirichlet nor Helson. To these ends, we need an estimate.

THEOREM 6.2. *If $\|1 - \langle \cdot, x \rangle\|_E = \varepsilon$ then*

$$\|1 - \langle \cdot, x \rangle\|_{B(E)} \leq 2 \sin(\pi/2p)$$

where p is the largest odd integer such that

$$s^{-1}(\varepsilon) = 2 \sin^{-1}(\varepsilon/2) \leq \pi/p.$$

In particular,

$$\|1 - \langle \cdot, x \rangle\|_{B(E)} \leq 2\|1 - \langle \cdot, x \rangle\|_E.$$

PROOF. We assume for convenience that $x > 0$.

$|1 - \exp(i\gamma x)| \leq \varepsilon$ iff $|\sin(\gamma x/2)| \leq \varepsilon/2$ which occurs iff there is an integer k with $|\gamma x - 2k\pi| \leq 2 \sin^{-1}(\varepsilon/2)$. Thus, $\|1 - \langle \cdot, x \rangle\|_E \leq \varepsilon$ iff

$$E \subset \bigcup_{k=-\infty}^{\infty} \left[\frac{2k\pi}{x} - \frac{s^{-1}(\varepsilon)}{x}, \frac{2k\pi}{x} + \frac{s^{-1}(\varepsilon)}{x} \right].$$

Suppose this to be the case and let p be the largest odd integer with $s^{-1}(\varepsilon) \leq \pi/p$. Then

$$(5) \quad E \subset \bigcup_{k=-\infty}^{\infty} \left[\frac{2k\pi}{x} - \frac{\pi}{px}, \frac{2k\pi}{x} + \frac{\pi}{px} \right].$$

We return now to the notation of Lemma 5.1 and set $b = \pi/px$ so that

$$z_k = \frac{x}{2} - ((2k+1)/2b)\pi = N_k x$$

where N_k is an integer. If we now set $\mu = \sum c_k \delta_{z_k}$ as in Lemma 5.1 we see, on one hand, that

$$\hat{\mu}(\gamma) = 1 - \exp(i\gamma x) \quad \text{for } |\gamma| \leq \pi/px$$

and, on the other hand, that

$$\hat{\mu}(\gamma) = \sum c_k \exp(iN_k x \gamma)$$

has period $2\pi/x$. These observations, together with (5), show that $\hat{\mu}(\gamma) = 1 - \exp(i\gamma x)$ for all $\gamma \in E$. Since $\|\mu\| = \sum |c_k| = s(xb) = 2 \sin(\pi/2p)$, the result follows.

The idea of using odd integers p comes, partly, from [8, p. 107].

There now follows directly from the last two theorems:

COROLLARY 6.1. *Every Dirichlet set is a BAS set.*

The idea of Theorem 6.2 will now be used to construct a class of BAS sets. We would like to construct a set E in such a manner that there is a sequence $x_n \rightarrow \infty$ with

$$(6) \quad \|1 - \langle \cdot, x_n \rangle\|_E \leq \delta$$

for some small δ , but we do not want $\|1 - \langle \cdot, x_n \rangle\|_E$ to approach 0 because we want E *not* to be a Dirichlet set.

Now, as we have seen, for a fixed n (6) is equivalent to:

$$(7) \quad E \subset \bigcup_{k=-\infty}^{\infty} \left[\frac{2k\pi}{x_n} - \frac{s^{-1}(\delta)}{x_n}, \frac{2k\pi}{x_n} + \frac{s^{-1}(\delta)}{x_n} \right] = F_n,$$

say. We would like to take for E a compact subset of $\bigcap_1^\infty F_n$, but the x_n must be picked coherently to prevent this set from being too small.

We pick $\delta < 1$ so that $N = (2\pi + r)/r$ is integral where $r = s^{-1}(\delta)$. Let $x_0 > 0$ be arbitrary and let $x_n = N^n x_0$ for $n = 1, 2, \dots$. We set

$$E_0 = \left[-\frac{r}{x_0}, \frac{r}{x_0} \right],$$

$$E_1 = \left[-\frac{2\pi}{x_1} - \frac{r}{x_1}, \frac{2\pi}{x_1} + \frac{r}{x_1} \right] \cup \left[\frac{r}{x_1}, \frac{r}{x_1} \right] \cup \left[\frac{2\pi}{x_1} - \frac{r}{x_1}, \frac{2\pi}{x_1} + \frac{r}{x_1} \right]$$

and, in general, $E_n = F_n \cap E_{n-1}$ with F_n as in (7).

Let $L = 2r/x_0$. Because of the choice of δ and the definitions of N and x_n , it follows that E_n is the union of 3^n intervals each of length LN^{-n} . Moreover, each interval I in E_{n-1} is replaced in E_n by 3 intervals, each $1/N$ times the length of I , one starting at the left endpoint of I , one centered at the center of I and one ending at the right endpoint of I .

Thus, if we define $E = \bigcap_0^\infty E_n$, then E is a compact set of the sort called by Kahane and Salem [6, pp. 16–17] “un parfait homogène” of type $(3, 1/N)$.

THEOREM 6.3. *Let $\delta = 2 \sin(\pi/2q)$ where $2q \geq 10$ is an integer. Then E as constructed above is a BAS set which is neither a Helson set nor a Dirichlet set.*

PROOF. Note, first, that $s^{-1}(\delta) = \pi/q$ so that $N = 2q + 1$ is integral. By construction, we have $\|1 - \langle \cdot, x_n \rangle\|_E = \delta$ for all n , and thus Theorem 6.2 implies that $\|1 - \langle \cdot, x_n \rangle\|_{B(E)} \leq 2 \sin(\pi/10) < 1$. By Theorem 6.1, E is, therefore, a BAS set.

It is known that no “parfait symétrique” is a Helson set [6, p. 146]. E contains such a Cantor-like symmetric set (formed by excluding from E the “middle $1/N$ s”) and is, thus, not Helson.

That no “parfait homogène” is a Dirichlet set follows readily from the fact that for any Dirichlet set S there are sequences $a_j \rightarrow 0$ and $b_j \rightarrow \infty$ such that, for each j , S can be covered by intervals of length a_j with the distances

between successive covering intervals all less than $a_j b_j$. (See [5, p. 90].)

REMARKS. 1. At the cost of some simplicity in the construction of E , we could replace δ and N by δ_n and N_n , varying with n , taking care to keep the N_n integral and bounded.

2. The same lacunarity conditions as in the definition of BAS sets have been considered by Kahane in a different, though related, context. See [6, p. 160] where it is stated that symmetric sets similar to the set E constructed above have a strong uniqueness property. Indeed, they are contained in the zero-sets of nontrivial, arbitrarily sparse, absolutely convergent trigonometric series. (A similar result follows from our methods by looking at the difference between a fixed character λ_0 and a series involving a sparse set of frequencies distinct from λ_0 and converging on E to λ_0 .)

Thinness itself does not imply the BAS property. We recall that E is called an M_0 -set if E supports a measure whose Fourier transform vanishes at infinity; otherwise E is a U_0 -set. Λ is said to be relatively dense in the group G if there is a compact set K with $\Lambda + K = G$. Returning to general LCA groups we have

THEOREM 6.4. *If E is an M_0 -set and balayage is possible for (Λ, E) then Λ is relatively dense. In particular, every BAS set is a U_0 -set.*

PROOF. It suffices, by Theorem 2.4, to suppose that Λ is not relatively dense and show that $k'(\Lambda, E) = \infty$.

Let $\mu \in M(E)$ be a fixed, nonzero measure such that $\lim_{x \rightarrow \infty} \hat{\mu}(x) = 0$. Suppose $\varepsilon > 0$. Then, there is a compact set K such that $|\hat{\mu}(x)| < \varepsilon$ if $x \notin K$.

By assumption, $-K + \Lambda \neq G$. Let $x_0 \notin -K + \Lambda$, and define σ by $d\sigma(\gamma) = \langle \gamma, -x_0 \rangle d\mu(\gamma)$. Then $\sigma \in M(E)$ and $\hat{\sigma}(x) = \hat{\mu}(x - x_0)$. Thus, if $\lambda \in \Lambda$ then $\lambda - x_0 \notin K$ so that $|\hat{\sigma}(\lambda)| = |\hat{\mu}(\lambda - x_0)| < \varepsilon$. Now, $\hat{\sigma} \in \mathcal{G}(E)^\perp$ because if $h \in \mathcal{G}(E)$ then $\int_G h \hat{\sigma} dx = \int_\Gamma \hat{h} d\sigma = \int_E 0 = 0$. Also, $\|\sigma\|_G = \|\mu\|_G$.

Thus $k'(\Lambda, E) \geq \|\hat{\sigma}\|_G / \|\hat{\sigma}\|_\Lambda \geq \|\mu\|_G / \varepsilon$. Since ε is arbitrary, $k'(\Lambda, E) = \infty$, proving the theorem.

We can now see that not every "parfait homogène" E is a BAS set, even if its ratio of dissection $\theta (= 1/N$ in our case) is small enough. Indeed, if $1/\theta$ is not a Pisot number (an algebraic integer all of whose conjugates have modulus less than 1) then E is an M_0 -set [6, Chapter VI]. It would be interesting to know whether some homogeneous U_0 -set with $1/\theta$ an irrational Pisot number is a BAS set.

COROLLARY 6.2. *If balayage is possible for (Λ, E) where E has positive Haar measure, then Λ is relatively dense.*

PROOF. Such an E is a M_0 -set.

COROLLARY 6.3. *If G is a nondiscrete, metrisable LCA group, then there is a perfect, strongly independent set $E \subset G$ with the property that in order for balayage to be possible for (Λ, E) , Λ must be relatively dense.*

PROOF. Varopoulos [11, Theorem R] has shown that G contains such a set E which is also an M_0 -set.

ADDED IN PROOF. We have recently realized that many results of our §§2 and 6 were known to Kahane. Indeed [5, p. 150] gives a result equivalent to our Theorem 2.4 but phrased in terms of pseudomeasures. (Kahane omits the proof but says that it follows from the result we quoted as Theorem 2.3.) Kahane then remarks (using a different terminology) that the possibility of balayage for (Λ, E) leads to results, such as the one of his referred to after our Theorem 6.3, on E 's being contained in the zero sets of certain trigonometric sets. Indeed, in proving that result [6, p. 160], Kahane constructed BAS sets. Our construction of BAS sets seems less involved than Kahane's. His method, however, leads to results on both the possibility and impossibility of balayage with Λ sparse but not arbitrarily sparse.
