ISOTOPING MAPPINGS TO OPEN MAPPINGS

BY

JOHN J. WALSH

ABSTRACT. Let f be a quasi-monotone mapping from a compact, connected manifold M^m ($m > 3$) onto a space Y ; then there is an open mapping g from M onto Y such that, for each $y \in Y$, $g^{-1}(y)$ is not a point and $g^{-1}(y)$ and $f^{-1}(y)$ are equivalently embedded in M (in particular, $g^{-1}(y)$ and $f^{-1}(y)$ have the same shape). Applying the result with f equal to the identity mapping on M yields a continuous decomposition of M into cellular sets each of which is not a point.

Let M^m be a compact, connected topological manifold of dimension $m > 3$; let f be a mapping from M onto a metric space Y satisfying: for each open, connected set $U \subseteq Y$, each component of $f^{-1}(U)$ is mapped onto U by f (such mappings are exactly the quasi-monotone or, equivalently, the quasi-open mappings of Whyburn [Why-1], [Why-2]; in particular, monotone mappings are quasi-open). The main result of this paper is that f can be approximated by an *open* mapping g from M onto Y satisfying for each $y \in Y$: (i) $g^{-1}(y)$ is not a point and (ii) $g^{-1}(y)$ and $f^{-1}(y)$ are equivalently embedded in M (in particular, $g^{-1}(y)$ and $f^{-1}(y)$ have the same shape). Even for the case $f = \text{id}_M$ (i.e., the identity mapping of M), this result yields the nontrivial fact that there is a continuous decomposition of M into cellular sets each of which is not a point. Continuous decompositions of the plane into nondegenerate cellular sets were constructed by Anderson [A-4] and Sosinski [So]. In [A-1], R. D. Anderson announced that the plane can be filled up with a continuous collection of pseudoarcs; however, he never published a proof. The results of this paper were inspired by Theorem II announced by Anderson in [A-1] (Theorem II appears in this paper as Corollary (1.1)).

The techniques used in this paper are reminiscent of those used by Anderson [A-2], [A-3], [A-4], by D. Wilson [Wi-1], [Wi-2], and by Walsh [Wa-1], [Wa-2].

The main result of this paper is stated in §1; in addition, in §1 we show that the main result is a consequence of an apparently weaker result. The proof of this latter result forms the bulk of this paper and is the content of §§5 and 6; §5 contains a technical device and §6 contains the actual proof. In §2, some

Key words and phrases. Open mapping, monotone mapping, manifold, cellular.

fundamental properties of brick partitions are stated; also a filtration obtained from a brick partition is described.

§§3 and 4 contain the proof of a very modest version of the main result. These two sections are included strictly for pedagogic reasons; specifically, it is useful to have Proposition (4.2) for comparison when discussing the difficulties faced in proving Proposition (6.1).

TERMINOLOGY. All spaces considered are assumed to be metric and all spaces of functions are to be given the uniform topology; in particular, for mappings (= continuous functions) between compact spaces the topology is given by the supremum metric. All metrics will be denoted $d(\cdot, \cdot)$. M^m will denote a compact, connected topological manifold of dimension m possibly with boundary (denoted ∂M). A set is *nondegenerate* if it is not a point. $\text{Int}(\cdot)$, $\text{cl}(\cdot)$, and $\text{diam}(\cdot)$ will refer to the topological interior, the closure, and the diameter of a set, respectively. (At times, we will also denote the closure of a set K by $\bar{K}$.) If A is a collection of sets, then A^* is the union of members of A and $\mu(A)$, the mesh of A , is the supremum of the diameters of the members of A . We will abusively use $\cap \{A_\gamma | \gamma \in \Gamma\}$ to denote $\bigcap_{\gamma \in \Gamma} A_\gamma$.

An ordered collection $(A_1, \dots, A_n)$ is a *chain* provided $A_i = A_j$ only if $i = j$ and $A_i \cap A_{i-1} \neq \emptyset$ for $i = 2, \dots, n$ (this is *not the standard use* of the term chain since we are permitting $A_i \cap A_j \neq \emptyset$ even if $|i - j| > 1$). A collection A *refines* a collection B if each set in A is contained in a set of B ; A is called a *refinement* of B . A sequence $\{A_n\}_{n=1}^\infty$ is *nested* provided $A_1 \supseteq A_2 \supseteq A_3 \dots$.

Let f be a mapping from X onto Y ; f is *open* provided $f(U)$ is open for each set $U \subseteq X$, f is *monotone* provided each $f^{-1}(y)$ is connected, and f is *quasi-open* or *quasi-monotone* provided for each open, connected set $V \subseteq Y$ if U is a connected component of $f^{-1}(V)$, then $f(U) = V$ (for mappings between compact, locally connected spaces the above definition of quasi-open and quasi-monotone coincides with standard definition of each; see [Why-2, p. 110] and [Why-1, p. 152]). Two further facts which we need from [Why-2] and [Why-1] are: (i) if f is a quasi-open mapping between compact, locally connected spaces and $f = l \circ m$ is the monotone-light factorization of f , then l is open; (ii) if $\{f_n\}_{n=1}^\infty$ is a sequence of quasi-open mappings between compact, locally connected spaces and $f = \lim_{n \rightarrow \infty} f_n$, then f is quasi-open.

By an *isotopy* of X we mean a path $\{h_t\}_{t \in [a, b]}$ or $\{h_t\}_{t \in (a, b)}$ of self-homeomorphisms of X where $[a, b]$ and (a, b) are subintervals of $[0, \infty)$. The statement *let $\beta = \beta_1 \cup \beta_2 \cup \dots \cup \beta_n$ be an arc* will mean that β is an arc (we use β to denote both the mapping and its image) and the β_i 's are subarcs with $\beta_i \cap \beta_{i+1}$ a single point for $i = 1, \dots, n - 1$ and with the β_i 's covering β ; $\beta(0)$ and $\beta_1(0)$ (resp., $\beta(1)$ and $\beta_n(1)$) denote the endpoint of β contained in β_1 (resp., β_n).

Let f be a mapping from X onto Y ; a closed subset $K \subseteq Y$ with $\text{int}(K) = \emptyset$ is called f -admissible provided $\text{int}(f^{-1}(K)) = \emptyset$. We say that f is admissible if each closed subset $K \subseteq Y$ with $\text{int}(K) = \emptyset$ is f -admissible (observe that open mappings are admissible).

The support of an isotopy $\{h_t\}_{t \in [a,b]}$ is denoted $\text{supp}(\{h_t\})$ and is equal to $\text{cl}(\{x \mid \text{for some } t \in [a, b], h_t(x) \neq x\})$.

Let A and B be closed subsets of a manifold M^m ; then A and B are equivalently embedded provided there is an isotopy $\{h_t\}_{t \in [0, \infty)}$ of M satisfying: (i) for each neighborhood V of A there is a neighborhood U of B and a t_0 with $A \subseteq h_t(U) \subseteq V$ for all $t \geq t_0$; (ii) for each neighborhood U of B there is a neighborhood V of A and a t_0 with $B \subseteq h_t^{-1}(V) \subseteq U$ for all $t \geq t_0$.

Let A be a collection of sets and let B be a set; define $\text{st}^0(B, A) = \{a \in A \mid a \subseteq B\}$, $\text{st}^1(B, A) = \{a \in A \mid a \cap B \neq \emptyset\}$, and, inductively for $i \geq 2$, $\text{st}^i(B, A) = \text{st}^1(\text{st}^{i-1}(B, A)^*, A)$; at times we will use $\text{st}(B, A)$ in place of $\text{st}^1(B, A)$.

1.

MAIN THEOREM. Let M^m be a compact, connected manifold with $m \geq 3$, let f be a quasi-open (equiv., quasi-monotone) mapping of M onto a space Y , and let $\varepsilon > 0$. Then there is an isotopy $\{h_t\}_{t \in [0, \infty)}$ of M satisfying: (i) $h_0 = \text{identity}$; (ii) $\lim_{t \rightarrow \infty} f \circ h_t = g$ exists and g is open; (iii) for each $t \in [0, \infty)$, $d(f, f \circ h_t) < \varepsilon$; (iv) for each $y \in Y$, each component of $g^{-1}(y)$ is nondegenerate and $g^{-1}(y)$ and $f^{-1}(y)$ are equivalently embedded in M .

REMARK. It will be clear from the proof of the Main Theorem that if A is a closed subset of M with $\dim(A) \leq m - 2$ (we are referring to the covering dimension of A), then we can assume that, for $t \in [0, \infty)$, $h_t|_{\partial M \cup A}$ equals the identity and, hence, that $f|_{\partial M \cup A} = g|_{\partial M \cup A}$.

The following corollary was announced by R. D. Anderson [A-1] but a proof was never published.

(1.1) **COROLLARY.** If f is a monotone mapping from M^m ($m \geq 3$) onto Y , then there is a monotone open mapping g from M onto Y .

REMARK. The author proved a version of (1.1) in [Wa-1, Corollary (3.7.2)] with the additional assumption that Y be a polyhedron; however, the monotone open mapping obtained in [Wa-1] is not obtained by an isotopy of M and definitely does not satisfy condition (iv) in the Main Theorem.

We can quickly reduce the Main Theorem to the case where f is monotone as follows. Let $f = l \circ m$ be the monotone-light factorization of f ; the Main Theorem applied to the monotone mapping m yields an isotopy of M which also "works" for f .

The remainder of this section deals with showing that the fact that $\lim_{t \rightarrow \infty} f \circ h_t = g$ implies that $f^{-1}(y)$ and $g^{-1}(y)$ are equivalently embedded. The proof of the following lemma is left to the reader.

(1.2) LEMMA. *Let X and Y be compact metric spaces, let $y \in Y$, and let V be a neighborhood of y . Then there is an $\varepsilon > 0$ such that, for any pair of mappings f, g from X onto Y with $d(f, g) < \varepsilon$, $g^{-1}(y) \subseteq f^{-1}(V)$.*

The following proposition is probably known and is certainly in the spirit contained in [K-L].

(1.3) PROPOSITION. *Let $\{h_t\}_{t \in [0, \infty)}$ and $\lim_{t \rightarrow \infty} f \circ h_t = g$ be as in the Main Theorem. Let $y \in Y$, let $\{W_i\}_{i=1}^{\infty}$ be a sequence of open neighborhoods of $f^{-1}(y)$ with $\overline{W_i} \subseteq W_{i-1}$ and with $f^{-1}(y) = \bigcap_{i=1}^{\infty} W_i$, and let $\varepsilon > 0$. Then there is an integer k and a number $s > 0$ (both depending on ε and y) such that $W_k \subseteq N_{\varepsilon}(f^{-1}(y))$ and, for each $t > s$,*

$$g^{-1}(y) \subseteq h_t^{-1}(W_k) \subseteq N_{\varepsilon}(g^{-1}(y)).$$

PROOF. Let $U \subseteq g(N_{\varepsilon}(g^{-1}(y)))$ be an open neighborhood of y with $g^{-1}(U) \subseteq N_{\varepsilon}(g^{-1}(y))$. Applying (1.2) with $V = U$, there is $t' > 0$ such that, for $t > t'$, $(f \circ h_t)^{-1}(y) \subseteq g^{-1}(U)$. Choose k such that $W_k \subseteq N_{\varepsilon}(f^{-1}(y))$, $f(W_k) \subseteq U$, and $(f \circ h_t)^{-1}(f(W_k)) \subseteq g^{-1}(U)$ for $t > t'$. Let $U' \subseteq f(W_k)$ be an open neighborhood of y with $f^{-1}(U') \subseteq W_k$. Applying (1.2) with $V = U'$, there is $s > t'$ such that, for $t > s$, $g^{-1}(y) \subseteq (f \circ h_t)^{-1}(U')$. Observe that if $t > s$, then

$$\begin{aligned} g^{-1}(y) &\subseteq (f \circ h_t)^{-1}(U') = h_t^{-1}(f^{-1}(U')) \subseteq h_t^{-1}(W_k) \\ &\subseteq h_t^{-1}(f^{-1} \circ f(W_k)) \subseteq g^{-1}(U) \subseteq N_{\varepsilon}(g^{-1}(y)); \end{aligned}$$

hence, the proof is complete.

REMARK. Since $\lim_{t \rightarrow \infty} f \circ h_t = g$, it follows that $\lim_{t \rightarrow \infty} g \circ h_t^{-1} = f$; applying Proposition (1.3) to the latter yields the conclusion in (1.3) with the roles of f and g interchanged and with h_t^{-1} in place of h_t .

Armed with Proposition (1.3) and this remark it follows easily that $f^{-1}(y)$ and $g^{-1}(y)$ are equivalently embedded in M . The purpose of introducing the concept of "equivalently embedded" is to give emphasis to the strong relationship between the point inverses of g and those of f ; this paper contains no further development of the concept.

2. Throughout this section Y will denote a compact, connected, locally connected metric space. A *brick partition* $\mathcal{G}$ for Y is a finite collection of pairwise disjoint open connected (nonempty) subsets of Y satisfying: (i) $\mathcal{G}^*$ is dense in Y and $g = \text{int}(\bar{g})$ for each $g \in \mathcal{G}$; (ii) if U is an open subset of Y and $g, g' \in \mathcal{G}$ with $\bar{g} \cap \bar{g}' \cap U \neq \emptyset$, then there is a point $y \in \bar{g} \cap \bar{g}' \cap U$

with $y \in \text{int}(\bar{g} \cup \bar{g}')$. (We have omitted mention of a metric related condition which the elements of $\mathcal{G}$ must also satisfy; we will not need this condition; see [Bi, p. 304].) By a *closed brick partition*, we will mean a collection consisting of the closures of the elements of a brick partition.

In [Bi], Bing proves that Y has a sequence $\{\mathcal{G}_i\}_{i=1}^{\infty}$ of brick partitions with $\mathcal{G}_i$ refining $\mathcal{G}_{i-1}$ and with $\lim_{i \rightarrow \infty} \mu(\mathcal{G}_i) = 0$. We will need the following slightly stronger form of this result. Let f be a mapping from a compact metric space X onto Y (we must assume that Y is not a point); a brick partition $\mathcal{G}$ is *f-admissible provided* $\{\bar{g} - g | g \in \mathcal{G}\}^*$ is *f-admissible*. We assert that for each such mapping f there is a sequence $\{\mathcal{G}_i\}_{i=1}^{\infty}$ of brick partitions for Y as above satisfying the additional requirement that each $\mathcal{G}_i$ is *f-admissible*. The proof of this assertion can be extracted from [Bi] by recalling that the collection $W - (W'_0 \cup \dots \cup W'_n)$ constructed in the proof of Theorem 5 on p. 308 of [Bi], is uncountable; this fact makes it possible to choose the brick partitions in Theorems 5–8 in [Bi] to be *f-admissible*.

Given a closed brick partition $\mathcal{G}$ of Y , we can obtain a filtration of Y as follows. Let $\mathcal{G} = \{g_1, \dots, g_q\}$; let

$$\mathcal{Q} = \{(u_1, \dots, u_k) | 1 \leq u_1 < u_2 < \dots < u_k \leq q; g_{u_1} \cap \dots \cap g_{u_k} \neq \emptyset;$$

$$\text{if } g_s \notin \{g_{u_1}, \dots, g_{u_k}\},$$

$$\text{then } g_s \cap (g_{u_1} \cap \dots \cap g_{u_k}) \neq g_{u_1} \cap \dots \cap g_{u_k}\}.$$

If $x = (u_1, \dots, u_k) \in \mathcal{Q}$ then let $|x| = g_{u_1} \cap \dots \cap g_{u_k}$ and call k the length of x . Partially order $\mathcal{Q}$ by defining $x = (u_1, \dots, u_k) \leq x' = (u'_1, \dots, u'_k)$ provided $|x| \subseteq |x'|$; we leave to the reader to check that we have a partial ordering. Let $I(\mathcal{Q})$ be the length of the longest chain in $\mathcal{Q}$; let $\mathfrak{M}_1 = \{\text{minimal elements of } \mathcal{Q}\}$; and, inductively for $t = 2, \dots, I(\mathcal{Q}) - 1$, let $\mathfrak{M}_t = \{\text{minimal elements of } \mathcal{Q} - \mathfrak{M}_{t-1} \text{ which do not have length one}\}$. Let $\mathfrak{M}_{I(\mathcal{Q})} = \{\text{elements in } \mathcal{Q} \text{ with length one}\}$.

3. The following proposition is well known (e.g., see Proposition 1 in [Wi-1]); we will use it in the next section. The proof is left to the reader.

(3.1) PROPOSITION. Let X and Y be compact metric spaces and let $\{F_n\}_{n=1}^{\infty}$ and $\{K_n\}_{n=1}^{\infty}$ be two sequences of finite collections of compact sets satisfying:

(3.1.1) For each n , $K_n^* = Y$ and $F_n^* = X$; and $\lim_{n \rightarrow \infty} \mu(K_n) = 0$.

(3.1.2) There exists a one-to-one and onto function $T_n: F_n \rightarrow K_n$ such that:

(a) For $n \geq 2$, if $f_n \in F_n$, $f_{n-1} \in F_{n-1}$ with $f_n \subseteq f_{n-1}$, then $T_n(f_n) \subseteq T_{n-1}(f_{n-1})$.

(b) If $x \in X$, then there is a sequence $\{f_n\}_{n=1}^{\infty}$ with $x \in f_n \in F_n$ and with, for $n \geq 2$, $f_n \subseteq f_{n-1}$.

(c) If $y \in Y$, then there is a sequence $\{k_n\}_{n=1}^{\infty}$ with $y \in k_n \in K_n$ and with, for $n \geq 2$, $k_n \subseteq k_{n-1}$ and $T_n^{-1}(k_n) \subseteq T_{n-1}^{-1}(k_{n-1})$.

(3.1.3) If $f_n^1, \dots, f_n^q \in F_n$ and $f_n^1 \cap \dots \cap f_n^q \neq \emptyset$, then $T_n(f_n^1) \cap \dots \cap T_n(f_n^q) \neq \emptyset$. Then there exists a mapping g from X onto Y defined by

$$g\left(\bigcap_{n=1}^{\infty} f_n\right) = \bigcap_{n=1}^{\infty} T_n(f_n)$$

for each nested sequence $\{f_n\}_{n=1}^{\infty}$ with $f_n \in F_n$.

4. The following theorem is a modest version of the Main Theorem; the proof of Theorem (4.1) is based on Proposition (4.2) and is presented at the end of this section.

(4.1) THEOREM. Assume the hypothesis of the Main Theorem. Then there is an isotopy $\{h_t\}_{t \in [0, \infty)}$ and a mapping $g = \lim_{t \rightarrow \infty} (f \circ h_t)$ satisfying all the conclusions of the Main Theorem except that, in place of g being open, we have that g is admissible.

(4.2) PROPOSITION. Let M^m be a compact, connected manifold with $m > 3$, let f be a monotone mapping of M onto Y , and let $\varepsilon > 0$. For each positive integer n , there is a monotone mapping H_n from M onto Y and a H_n -admissible closed brick partition J_n of Y satisfying:

(4.2.1) $\mu(J_1) < \varepsilon/3$ and, for $n > 2$, J_n refines J_{n-1} and $\mu(J_n) < \varepsilon_n/2^n$ where

$$\xi_n = \min\{\xi_2, \dots, \xi_{n-1},$$

$$\min\{d(j_{n-1}, (J_{n-1} - \text{st}(j_{n-1}, J_{n-1})))^* | j_{n-1} \in J_{n-1}\}\}.$$

(4.2.2) For $n > 2$, if $j_n \in J_n$ and $j_{n-1} \in J_{n-1}$ with $j_n \subseteq j_{n-1}$, then

$$H_n^{-1}(\text{int}(j_n)) \subseteq H_{n-1}^{-1}(\text{int}(j_{n-1})) \subseteq N_{1/2^n}(H_{n-1}^{-1}(\text{int}(j_{n-1}))).$$

PROOF. Let $\{\mathcal{G}_i\}_{i=1}^{\infty}$ be a sequence of f -admissible closed brick partitions of Y with $\mathcal{G}_i$ refining $\mathcal{G}_{i-1}$ and with $\lim_{i \rightarrow \infty} \mu(\mathcal{G}_i) = 0$. Choose i_1 such that $\mu(\mathcal{G}_{i_1}) < \varepsilon/3$; let $J_1 = \mathcal{G}_{i_1}$ and $H_1 = f$. We will now present the construction of the $n = 2$ stage; the method for going from the n th stage to the $(n + 1)$ st stage is essentially the same construction.

Choose $i_2 > i_1$ such that $\mu(\mathcal{G}_{i_2}) < \xi_2/2^2$ and let $J_2 = \mathcal{G}_{i_2}$. Let $\Gamma = \{(j_2, j_1) \in J_2 \times J_1 | j_2 \subseteq j_1\}$. For each $\gamma = (j_2, j_1) \in \Gamma$, let $\beta_\gamma \subseteq H_1^{-1}(\text{int}(j_1))$ be an arc with $\beta_\gamma(0) \in H_1^{-1}(\text{int}(j_2))$ and with $H_1^{-1}(\text{int}(j_1)) \subseteq N_{1/2^2}(\beta_\gamma)$; and let $U_\gamma \subseteq H_1^{-1}(\text{int}(j_1))$ be an open neighborhood of β_γ . We can assume that the U_γ 's are pairwise disjoint. Let $\{k_t^2\}_{t \in [0, 1]}$ be an isotopy of M with $k_0^2 = \text{identity}$, with $\text{supp}(\{k_t^2\}_{t \in [0, 1]}) \subseteq \{U_\gamma | \gamma \in \Gamma\}^*$, and with $\beta_\gamma \subseteq (H_1 \circ k_1)^{-1}(\text{int}(j_2))$ for each $\gamma = (j_2, j_1) \in \Gamma$.

(4.3) REMARK. We need to be sure that each of the β_γ 's is chosen so that any neighborhood of $\beta_\gamma(0)$ can be "pulled over" the entire arc β_γ . There is no difficulty in making such choices; henceforth, we will implicitly assume that all arcs used are so chosen.

The $n = 2$ stage is completed by letting $H_2 = H_1 \circ k_1^2$. The inductive step is done similarly by choosing $i_n > i_{n-1}$ such that $\mu(\mathcal{G}_{i_n}) < \xi_n/2^n$ and letting $J_n = \mathcal{G}_{i_n}$ and $\Gamma = \{(j_n, j_{n-1}) \in J_n \times J_{n-1} | j_n \subseteq j_{n-1}\}$, and using H_{n-1} in place of H_1 and $N_{1/2^n}(\beta_\gamma)$ in place of $N_{1/2^2}(\beta_\gamma)$.

PROOF OF THEOREM (4.1). (4.4) Define the isotopy $\{h_t\}_{t \in [0, \infty)}$ as follows. Let h_t = identity for $t \in [0, 1]$ and, for each integer $n \geq 1$, if $t \in [n, n+1]$, then let $h_t = k_1^2 \circ k_1^3 \circ \cdots \circ k_1^n \circ k_{t-n}^{n+1}$. Observe that $H_n = f \circ h_n$. We will now verify that $\lim_{n \rightarrow \infty} H_n$ exists; we leave to the reader to verify that $\lim_{t \rightarrow \infty} (f \circ h_t)$ exists.

Let $K_n = \{j_n^1 \cup \cdots \cup j_n^q | j_n^1 \cap \cdots \cap j_n^q \neq \emptyset \text{ and } j_n \cap (j_n^1 \cap \cdots \cap j_n^q) = \emptyset \text{ for each } j_n \in J_n - \{j_n^1, \dots, j_n^q\}\}$. Let $F_n = \{\text{cl}(H_n^{-1}(\text{int}(k_n))) | k_n \in K_n\}$ and let $T_n(\text{cl}(H_n^{-1}(\text{int}(k_n)))) = k_n$. It is easily verified that the sequence of triples $T_n: F_n \rightarrow K_n$ satisfies the hypothesis of Proposition (3.1); it is useful to have the observation that, since J_n is H_n -admissible, if $k_n = j_n^1 \cup \cdots \cup j_n^q \in K_n$, then

$$\text{cl}(H_n^{-1}(\text{int}(k_n))) = \text{cl}(H_n^{-1}(\text{int}(j_n^1))) \cup \cdots \cup \text{cl}(H_n^{-1}(\text{int}(j_n^q))).$$

Let g be the mapping defined in (3.1); we now check that $\lim_{n \rightarrow \infty} H_n = g$. Let $\delta > 0$ and let n_0 be such that $\mu(K_n) < \delta$ for $n \geq n_0$. Let $x \in M$ and let $\{f_n\}_{n=1}^\infty$ be a nested sequence with $f_n \in F_n$ and $x \in \bigcap_{n=1}^\infty f_n$. For each n , $H_n(x) \in T_n(f_n)$ and, since $g(x) = \bigcap_{n=1}^\infty T_n(f_n)$, $g(x) \in T_n(f_n)$. Therefore, if $n \geq n_0$, then $d(g(x), H_n(x)) < \delta$.

We now show that g is admissible. Let L be a closed subset of Y with $\text{int}(L) = \emptyset$. Let $x \in g^{-1}(L)$ and let $\eta > 0$; we will now produce $x' \in N_\eta(x)$ with $g(x') \notin L$. Let n_0 be such that $\sum_{n \geq n_0} 1/2^n < \eta$. Let $j_{n_0} \in J_{n_0}$ with $N_{1/2^{n_0}}(x) \cap H_{n_0}^{-1}(\text{int}(j_{n_0})) \neq \emptyset$ and let $n_1 > n_0$ be such that there is a $j_{n_1} \in J_{n_1}$ with $j_{n_1} \subseteq j_{n_0}$ and $\text{st}(j_{n_1}, J_{n_1})^* \cap L = \emptyset$. Let $j_{n_0}, j_{n_0+1}, \dots, j_{n_1}$ be a nested sequence with $j_{n_0+i} \in J_{n_0+i}$ for $i = 1, \dots, n_1 - n_0$. Let $x_{n_0} \in N_{1/2^{n_0}}(x) \cap H_{n_0}^{-1}(\text{int}(j_{n_0}))$ and, inductively for $i = n_0 + 1, \dots, n_1$, recalling condition (4.2.2), let $x_i \in N_{1/2^i}(x_{i-1}) \cap H_i^{-1}(\text{int}(j_i))$. Observe that $d(x, x_{n_1}) < \sum_{i=n_0}^{n_1} 1/2^i < \eta$ and it is easy to verify that $g(x_{n_1}) \in \text{st}(j_{n_1}, J_{n_1})^*$; let $x' = x_{n_1}$.

To be sure that each $g^{-1}(y)$ is nondegenerate, we must change the construction in the proof of Proposition (4.2) as follows. For each $j_1 \in J_1$, let $B_{j_1}^1$ and $B_{j_1}^2$ be disjoint nonempty, open subsets of $H_1^{-1}(\text{int}(j_1))$. A more careful choice of the β_γ 's will insure that for each $n \geq 1$, if $j_n \in J_n$ and $j_n \subseteq j_1 \in J_1$, then $H_n^{-1}(\text{int}(j_n)) \cap B_{j_1}^i \neq \emptyset$, $i = 1, 2$. We leave to the reader to verify that this modification guarantees that each $g^{-1}(y)$ is nondegenerate.

5. Proposition (5.1) below is an embellished version of Proposition (3.1) and is used to produce open mappings ((5.1) appears as Proposition 2 in Wilson's paper [Wi-1] and the reader is referred there for a proof). Proposition (5.2) is

the technical device used to govern the construction contained in the next section; (5.2) is a variation of Wilson's Proposition 3 in [W1-1]. Both these propositions have their genesis in Anderson's work [A-2], [A-3], [A-4].

(5.1) PROPOSITION. *Assume in addition to the hypothesis of Proposition (3.1) that:*

(5.1.1) *If $k_n, k'_n \in K_n$ and $k_n \cap k'_n \neq \emptyset$, then*

$$T_n^{-1}(k_n) \cap T_n^{-1}(k'_n) \neq \emptyset.$$

(5.1.2) *There is $a > 0$ such that if $f_n, f'_n \in F_n$ and $f_n \cap f'_n \neq \emptyset$, then*

$$f_n \subseteq N_{a/2^n}(f'_n).$$

(5.1.3) *There is $b > 0$ such that if $f_n \in F_n$ and $f_{n-1} \in F_{n-1}$ with $f_n \subseteq f_{n-1}$, then*

$$f_{n-1} \subseteq N_{b/2^n}(f_n).$$

Then the mapping g constructed will be open.

(5.2) PROPOSITION. *Let X and Y be compact metric spaces and let $\{J_n\}_{n=1}^\infty$ and $\{P_n\}_{n=1}^\infty$ be two sequences of finite collection of compact sets satisfying:*

$$J_n^* = Y \quad \text{and} \quad P_n^* = X; \quad \lim_{n \rightarrow \infty} \mu(J_n) = 0. \quad (5.2.1)$$

(5.2.2) *The members of J_n (resp., P_n) have pairwise disjoint nonempty interiors; and, for each $j_n \in J_n$, $j_n = \text{cl}(\text{int}(j_n))$.*

(5.2.3) *There is a one-to-one and onto function $R_n: J_n \rightarrow P_n$ such that:*

(i) *if $p_n^1, \dots, p_n^q \in P_n$ and $p_n^1 \cap \dots \cap p_n^q \neq \emptyset$, then $R_n^{-1}(p_n^1) \cap \dots \cap R_n^{-1}(p_n^q) \neq \emptyset$;*

(ii) *if $j_n, j'_n \in J_n$ and $j_n \cap j'_n \neq \emptyset$, then $R_n(j_n) \cap R_n(j'_n) \neq \emptyset$.*

(5.2.4) *For $n \geq 2$, if $j_n \in J_n$ and $j_{n-1} \in J_{n-1}$ with $j_n \cap \text{int}(j_{n-1}) \neq \emptyset$, then $\text{int}(R_n(j_n)) \cap \text{int}(R_{n-1}(j_{n-1})) \neq \emptyset$.*

(5.2.5) *For $n \geq 2$, if $j_n \in J_n$, then $\cap \{j_{n-1} \in J_{n-1} | R_{n-1}(j_{n-1}) \cap R_n(j'_n) \neq \emptyset \text{ for some } j'_n \in \text{st}(j_n, J_n)\} \neq \emptyset$.*

(5.2.6) *There is $c > 0$ such that if $j_n, j'_n \in J_n$ and $j_n \cap j'_n \neq \emptyset$, then $R_n(j_n) \subseteq N_{c/2^n}(R_n(j'_n))$.*

(5.2.7) *There is a $d > 0$ such that, for $n \geq 2$, if $j_n \in J_n$ and $j_{n-1} \in J_{n-1}$ with $j_n \cap \text{int}(j_{n-1}) \neq \emptyset$, then $R_{n-1}(j_{n-1}) \subseteq N_{d/2^n}(R_n(j_n))$.*

Then, letting $K_n = \{j_n^1 \cup \dots \cup j_n^q | j_n^1 \cap \dots \cap j_n^q \neq \emptyset \text{ and } j_n \cap (j_n^1 \cap \dots \cap j_n^q) = \emptyset \text{ for } j_n \in J_n - \{j_n^1, \dots, j_n^q\}\}$, letting $F_n = \{R_n(j_n^1) \cup \dots \cup R_n(j_n^q) | j_n^1 \cup \dots \cup j_n^q \in K_n\}$ and letting $T_n(R_n(j_n^1) \cup \dots \cup R_n(j_n^q)) = j_n^1 \cup \dots \cup j_n^q$, the triples $T_n: F_n \rightarrow K_n$ satisfy the hypothesis of Proposition (5.1) with $a = 2c$ and $b = 4c + d$.

PROOF. It is easy to show that conditions (3.1.1), (3.1.3), and (5.1.1) hold and conditions (5.1.2) and (5.1.3) are direct consequences of (5.2.6) and (5.2.7).

CONDITION (3.1.2). (a) Let $f_n \in F_n$ and $f_{n-1} \in F_{n-1}$ with $f_n \subseteq f_{n-1}$. Suppose that $T_n(f_n) \not\subseteq T_{n-1}(f_{n-1})$; then there is $j_n \subseteq T_n(f_n)$ with $j_n \not\subseteq T_{n-1}(f_{n-1})$ and $j_{n-1} \not\subseteq T_{n-1}(f_{n-1})$ with $j_n \cap \text{int}(j_{n-1}) \neq \emptyset$. Property (5.2.4) implies that $f_n \cap \text{int}(R_{n-1}(j_{n-1})) \neq \emptyset$; since $\text{int}(R_{n-1}(j_{n-1})) \cap f_{n-1} = \emptyset$, we have the contradiction that $f_n \not\subseteq f_{n-1}$. Hence we must have $T_n(f_n) \subseteq T_{n-1}(f_{n-1})$.

CONDITION (3.1.2). (b) Let $x \in X$ and let $j_n^x \in J_n$ with $x \in R_n(j_n^x)$. Let $D_{n-1}^x = \{j_{n-1} \in J_{n-1} \mid \text{there is a } j_n \in \text{st}(j_n^x, J_n) \text{ with } R_{n-1}(j_{n-1}) \cap R_n(j_n) \neq \emptyset\}$. Property (5.2.5) implies that there is $k_{n-1}^x \in K_{n-1}$ with $(D_{n-1}^x)^* \subseteq k_{n-1}^x$. If $x \in R_{n-1}(j_{n-1})$, then property (5.2.4) implies that $j_{n-1} \in D_{n-1}^x$; hence, $j_{n-1}^x \subseteq k_{n-1}^x$ and $x \in T_{n-1}^{-1}(k_{n-1}^x)$. Letting $f_{n-1}^x = T_{n-1}^{-1}(k_{n-1}^x)$, we will now show that a sequence $\{f_n^x\}$ chosen as above is nested. Since $T_n(f_n^x) \subset \text{st}(j_n^x, J_n)^*$, it suffices to show that $R_n(j_n) \subseteq f_{n-1}^x$ for each $j_n \in \text{st}(j_n^x, J_n)$. To this end, notice that if $j_n \in \text{st}(j_n^x, J_n)$ and $R_n(j_n) \cap R_{n-1}(j_{n-1}) \neq \emptyset$, then $j_{n-1} \in D_{n-1}^x$; therefore, $R_n(j_n) \subseteq f_{n-1}^x$.

CONDITION (3.1.2). (c) Let $y \in Y$ and let $j_n^y \in J_n$ with $y \in j_n^y$. Let $E_{n-1}^y = \{j_{n-1} \in J_{n-1} \mid \text{there is a } j_n \in \text{st}(j_n^y, J_n) \text{ with } R_{n-1}(j_{n-1}) \cap R_n(j_n) \neq \emptyset\}$; let $k_{n-1}^y \in K_{n-1}$ with $(E_{n-1}^y)^* \subseteq k_{n-1}^y$ (property (5.2.5) guarantees that k_{n-1}^y exists). We leave to the reader to use (5.2.5) to verify that a sequence $\{k_n^y\}$ chosen as above is nested and that $T_n^{-1}(k_n^y) \subseteq T_{n-1}^{-1}(k_{n-1}^y)$.

6. Proposition (6.1) below together with Propositions (5.1) and (5.2) will be used to prove the Main Theorem in much the same manner that Propositions (4.2) and (3.1) were used to prove Theorem (4.1).

(6.1) PROPOSITION. Let M^m be a compact, connected manifold with $m \geq 3$, let f be a monotone mapping of M onto Y , and let $\varepsilon > 0$. For each positive integer n , there is a monotone mapping H_n from M onto Y and a H_n -admissible closed brick partition J_n of Y satisfying:

(6.1.1) $\mu(J_1) < \varepsilon/3$ and, for $n \geq 2$, J_n refines J_{n-1} and $\mu(J_n) < \xi_n/2^n$ where $\xi_n = \min\{\xi_2, \dots, \xi_{n-1}, \min\{d(j_{n-1}, (Y - \text{st}(j_{n-1}, J_{n-1})^*)) \mid j_{n-1} \in J_{n-1}\}\}$.

(6.1.2) For $n \geq 2$, if $j_n \in J_n$ and $j_{n-1} \in J_{n-1}$ with $j_n \cap j_{n-1} \neq \emptyset$, then $H_n^{-1}(\text{int}(j_n)) \cap H_{n-1}^{-1}(\text{int}(j_{n-1})) \neq \emptyset$.

(6.1.3) For $n \geq 2$, if $j_n \in J_n$, then $\cap \{j_{n-1} \in J_{n-1} \mid \text{cl}(H_{n-1}^{-1}(\text{int}(j_{n-1}))) \cap \text{cl}(H_n^{-1}(\text{int}(j_n))) \neq \emptyset \text{ for some } j'_n \in \text{st}(j_n, J_n)\} \neq \emptyset$.

(6.1.4) If $j_n, j'_n \in J_n$ with $j_n \cap j'_n \neq \emptyset$, then $H_n^{-1}(\text{int}(j_n)) \subseteq N_{1/2^n}(H_n^{-1}(\text{int}(j'_n)))$.

(6.1.5) For $n \geq 2$, if $j_n \in J_n$ and $j_{n-1} \in J_{n-1}$ with $j_n \cap j_{n-1} \neq \emptyset$, then $H_n^{-1}(\text{int}(j_{n-1})) \subseteq N_{1/2^n}(H_n^{-1}(\text{int}(j_n)))$.

DISCUSSION. Although the proof of Proposition (6.1) is long, the mapping H_n is obtained from H_{n-1} by a finite sequence of alterations with each individual alteration consisting of "pulling" a small neighborhood of one endpoint of an arc in M over the entire arc and "alongside" several other

arcs. The proof of Proposition (6.1) splits into three basic parts; first, in (6.2)–(6.4), we construct the partition J_n and develop a “bookkeeping system” (which is unfortunately very complicated) which contains a detailed description of each individual description of each individual alteration; second, in (6.5) we give a global description of the alterations used to obtain H_n from H_{n-1} (it is difficult to prove that H_n satisfies condition (6.1.4)ⁿ using the global description); in (6.6), we obtain H_n from H_{n-1} by a sequence of alterations each of which is part of an alteration described in (6.5) and, simultaneously, we prove that H_n satisfies condition (6.1.4)ⁿ.

The remainder of the discussion is devoted to: first, a comparison of Propositions (6.1) and (4.2) and a description of the central difficulty encountered in proving (6.1); second, a comparison of the approach used to prove Proposition (6.1) with those used in [Wa-1], [Wa-2] and [Wi-1], [Wi-2]; third, an outline of the proof of Proposition (6.1) for a special case and suggestions which should be helpful in reading the proof of Proposition (6.1).

A COMPARISON OF PROPOSITIONS (4.2) AND (6.1). Conditions (6.1.1) and (4.2.1) are exactly the same; part of condition (4.2.2) is retained in condition (6.1.5). In Proposition (4.2), if $j_n \subseteq j_{n-1}$, then $H_n^{-1}(\text{int}(j_n)) \subseteq H_{n-1}^{-1}(\text{int}(j_{n-1}))$ and condition (6.1.2) necessarily held; although it is necessary to state condition (6.1.2) explicitly, the construction is such that it is easily seen to hold. Conditions (6.1.3) and (6.1.4) represent the essential differences between Propositions (6.1) and (4.2). Condition (6.1.3) is needed to insure that the H_n 's converge to a function (the information needed is that if $H_n^{-1}(j_n) \cap H_{n-1}^{-1}(j_{n-1}) \neq \emptyset$, then j_n is “close to” j_{n-1}). Condition (6.1.4) guarantees that the H_n 's converge to an open mapping.

The major difficulty in the proof of Proposition (6.1) is to achieve condition (6.1.4) subject to the constraint imposed by condition (6.1.3). Condition (6.1.4) is extremely “delicate” since each time $H_{n-1}^{-1}(j_n)$ is altered it is necessary to alter $H_{n-1}^{-1}(j'_n)$ for each $j'_n \in \text{st}(j_n, J_n)$; this makes it necessary to alter $H_n^{-1}(j''_n)$ for each $j''_n \in \text{st}(j'_n, J_n)$ where $j'_n \in \text{st}(j_n, J_n) \dots$. The “bookkeeping system” established in (6.3) lists each alteration which is to be made; the complexity of the system results from the interdependence of various alterations.

A comparison of Proposition (6.1) and Proposition (3.1) in [Wa-1]. Those readers not familiar with [Wa-1] may skip this paragraph; *in this paragraph only* (3.1.·) will refer to conditions in Proposition (3.1) in [Wa-1]. The role of K_n 's and R_n 's in Proposition (3.1) is played by the H_n 's (i.e., we define K_n and R_n by letting $K_n = \{\text{cl}(H_n^{-1}(\text{int}(j_n))) | j_n \in J_n\}$ and letting $R_n(\text{cl}(H_n^{-1}(\text{int}(j_n)))) = j_n$). The first part of condition (3.1.3) is automatically satisfied and the second part is essentially condition (6.1.2). Conditions (3.1.2) and (3.1.4) are replaced by condition (6.1.3); condition (3.1.6) is replaced by condition

(6.1.5); and, condition (3.1.5) is replaced by condition (6.1.4). Notice that there is not a condition in Proposition (6.1) which plays the role of condition (3.1.7); the latter condition and the rule in (3.3) are used to achieve condition (3.1.5). There is a definite temptation to use a variation of (3.1.7) and (3.3) in the proof of Proposition (6.1) in order to achieve condition (6.1.4); and such an approach can be used to get condition (6.1.4) partially satisfied. This author's experience with several such approaches convinced him that if a method can be used to achieve condition (6.1.4) exactly, then the method can be used from the outset; i.e., without partially achieving condition (6.1.4) by the preliminary use of a variation of (3.1.7) and (3.3). (In fact, there is a precise sense in which the method used in proving Proposition (3.1) is a "nonisotopic" method.) Nevertheless, those familiar with [Wa-1], [Wa-2] and [Wi-1] can benefit by contemplating an approach to the proof of Proposition (6.1) based on the technique used therein.

AN OUTLINE OF THE PROOF OF PROPOSITION (6.1). Suppose that J_{n-1} and H_{n-1} have been constructed; since the information in $(6.1.1)^{n-1}-(6.1.5)^{n-1}$ is not needed in order to construct H_n and J_n , it is not necessary to know the method which was used to construct J_{n-1} and H_{n-1} . Let $\mathcal{Q}, \mathfrak{N}_1, \dots, \mathfrak{N}_{I(\mathcal{Q})}$ be the filtration of Y obtained from the partition J_{n-1} (see §2) and let $M_i = \{|x| \mid x \in \mathfrak{N}_i\}^*$, $i = 1, 2, \dots, I(\mathcal{Q})$. The partition J_n will be a union, $J_n^1 \cup \dots \cup J_n^{I(\mathcal{Q})}$, of pairwise disjoint collections with

$$M_1 \cup \dots \cup M_i \subseteq \text{int}((J_n^1 \cup \dots \cup J_n^i)^*) \quad \text{for } i = 1, 2, \dots, I(\mathcal{Q}).$$

For the remainder of the discussion, we are going to assume that Y is a 2 dimensional manifold (for convenience, without boundary) with the bricks in the partitions being 2-cells which intersect in arcs. In particular, $I(\mathcal{Q}) = 3$, M_1 is a collection of points, M_2 is a collection of 1-cells, and M_3 is a collection of 2-cells. (The only special property of 2-manifolds we want to use is that $I(\mathcal{Q}) = 3$; the case with $I(\mathcal{Q}) = 3$ is sufficiently complex in order to illustrate the approach which is used to achieve condition (6.1.4).) Recall that J_n will be the union of collections J_n^1, J_n^2 , and J_n^3 ; J_n^1 consists of bricks which intersect M_1 , J_n^2 consists of bricks which intersect $M_2 - (J_n^1)^*$, and J_n^3 consists of bricks which intersect $M_3 - (J_n^1 \cup J_n^2)^*$; see Figure 1. In Figure 1, notice that the bricks in J_n^2 (resp., J_n^3) are smaller than those in J_n^1 (resp., J_n^2); in fact, the actual difference in size is greater than the difference which is illustrated.

The collections J_n^1, J_n^2 , and J_n^3 are constructed inductively as follows.

Step 1. The collection J_n^1 is chosen as is indicated in Figure 1 with $M_1 \subseteq \text{int}((J_n^1)^*)$; note that each element of J_n^1 meets M_1 ; in addition, the diameter of the elements of J_n^1 should be "small". For each pair $j_n \in J_n^1$ and $j_{n-1} \in J_{n-1}$ with $j_n \cap j_{n-1} \neq \emptyset$, a m -ball $Q \subseteq H_{n-1}^{-1}(\text{int}(j_n))$ is chosen with diameter less than $1/2^{n+2}$ and an arc $\eta \subseteq H_{n-1}^{-1}(\text{int}(j_n \cup j_{n-1}))$ is chosen with one endpoint in Q and with $H_{n-1}^{-1}(\text{int}(j_{n-1}))$ contained in the $1/2^{n+1}$ neigh-

borhood of η . One alteration of H_{n-1} is to "pull" a small neighborhood of the endpoint of η in Q over the entire arc η . Each such arc is divided into subarcs whose diameters are less than $1/2^{n+2}$. Let E_1 be the maximum number of subarcs needed for any such arc and let $\mathfrak{E}_1 = E_1 + 1$. Throughout the construction the arcs (resp., m -balls) chosen should be pairwise disjoint; and the only intersections of arcs and m -balls are those specified.

FIGURE 1

Step 2. The collection J_n^2 is chosen as is indicated in Figure 1 with $M_2 \subseteq \text{int}((J_n^1 \cup J_n^2)^*)$, with each element of J_n^2 meeting M_2 , and such that if $j_n \in J_n^1$ and $(j_n^1, \dots, j_n^{\mathfrak{E}_1})$ is a chain of elements from J_n^2 with $j_n \cap j_n^1 \neq \emptyset$, then $j_n^1 \cup \dots \cup j_n^{\mathfrak{E}_1}$ is "close to" j_n . For each pair $j_n \in J_n^2$ and $j_{n-1} \in J_{n-1}$ with $j_n \cap j_{n-1} \neq \emptyset$, an m -ball Q and an arc η are chosen as in Step 1; for each such Q and η an alteration as described in Step 1 will be done. For each $j_n \in J_n^1$, each m -ball $Q \subseteq H_{n-1}^{-1}(\text{int}(j_n))$ previously chosen, and each chain $(j_n^1, \dots, j_n^{\mathfrak{E}_1})$ of elements from J_n^2 with $j_n \cap j_n^1 \neq \emptyset$ do the following: choose arcs $\alpha_1, \dots, \alpha_{\mathfrak{E}_1}$ and m -balls $Q_1, \dots, Q_{\mathfrak{E}_1}$ (the m -balls should have diameters less than $1/2^{n+2}$ with $Q_i \subseteq H_{n-1}^{-1}(\text{int}(j_n^i))$ for $i = 1, \dots, \mathfrak{E}_1$, with $\alpha_1 \subseteq H_{n-1}^{-1}(\text{int}(j_n \cup j_n^1))$ and one endpoint of α_1 in Q_1 and the other in Q , and with $\alpha_i \subseteq H_{n-1}^{-1}(\text{int}(j_n^i \cup j_n^{i-1}))$ and one endpoint of α_i in Q_i and the other in Q_{i-1} , $i = 2, \dots, \mathfrak{E}_1$. The α_i 's and Q_i 's are used to alter H_{n-1} as is indicated in Figure 2; for $i = 2, \dots, \mathfrak{E}_1$, $H_{n-1}^{-1}(\text{int}(j_n^i))$ is "pulled alongside" one fewer subarc of η than $H_{n-1}^{-1}(\text{int}(j_n^{i-1}))$ is "pulled alongside". The choice of $\mathfrak{E}_1$ is such that $H_{n-1}^{-1}(\text{int}(j_n^{\mathfrak{E}_1}))$ is not "pulled alongside" any of η .

FIGURE 2

Divide each arc chosen above (both the η 's and the α 's) into subarcs whose diameters are less than $1/2^{n+2}$. Let E_2 be the maximum number of subarcs needed for any such arc and let $\mathfrak{E}_2 = 1 + \mathfrak{E}_1 + \mathfrak{E}_1 \cdot E_2$.

Step 3. The collection J_n^3 is chosen as is indicated in Figure 1 with the property that if $j_n \in J_n^1 \cup J_n^2$ and $(j_n^1, \dots, j_n^{\mathfrak{E}_2})$ is a chain of elements from J_n^3 with $j_n \cap j_n^1 \neq \emptyset$, then $j_n^1 \cup \dots \cup j_n^{\mathfrak{E}_2}$ is "close to" j_n . For each pair $j_n \in J_n^3$ and $j_{n-1} \in J_{n-1}$ with $j_n \cap j_{n-1} \neq \emptyset$, an m -ball Q and an arc η are chosen as in Step 1; for each such Q and η , an alteration as described in Step 1 will be done. For each $j_n \in J_n^1 \cup J_n^2$, each m -ball $Q \subseteq H_{n-1}^{-1}(\text{int}(j_n))$ previously chosen, each chain $(j_n^1, \dots, j_n^{\mathfrak{E}_2})$ of elements from J_n^3 with $j_n \cap j_n^1 \neq \emptyset$, arcs $\alpha_1, \dots, \alpha_{\mathfrak{E}_2}$ and m -balls $Q_1, \dots, Q_{\mathfrak{E}_2}$ are chosen as in Step 2. (Since this is the last step in the construction of $J_n = J_n^1 \cup J_n^2 \cup J_n^3$, it is not necessary to subdivide the arcs chosen above.) Let $j_n \in J_n^1 \cup J_n^2$, let $Q \subseteq H_{n-1}^{-1}(\text{int}(j_n))$ be a m -ball previously chosen, and let $(j_n^1, \dots, j_n^{\mathfrak{E}_2})$ be a chain of elements from J_n^3 with $j_n \cap j_n^1 \neq \emptyset$. There are two "types" of Q 's. First, Q was paired with an arc η ; in this case, an alteration as described in Step 2 will be done. Second, Q was paired with an arc $\hat{\alpha}_i$ which was chosen in Step 2 for $\hat{j}_n^1 \in J_n^1$ and $(\hat{j}_n^1, \dots, \hat{j}_n^{\mathfrak{E}_1})$ a chain of elements from J_n^2 with $\hat{j}_n \cap \hat{j}_n^1 \neq \emptyset$; in this case, H_{n-1} will be altered as is indicated in Figure 3. Notice that the choice of $\mathfrak{E}_2$ is such that $H_{n-1}^{-1}(\text{int}(j_n^{\mathfrak{E}_2}))$ is not "pulled alongside" any of $\hat{\alpha}_i$.

The reader is encouraged to "sketch" a proof that condition (6.1.4)ⁿ will hold if the alterations indicated above are done (the above outline omits a few technical but important details). The approach to use is to show that if $j_n \cap j'_n \neq \emptyset$ and $j_{n-1} \in J_{n-1}$, then

$$H_n^{-1}(\text{int}(j'_n)) \cap H_{n-1}^{-1}(\text{int}(j_{n-1})) \subseteq N_{1/2^n}(H_n^{-1}(\text{int}(j_n))).$$

FIGURE 3

An important observation is that the alteration done with respect to the η 's guarantees that (6.1.5)^r holds for pairs j_n and j_{n-1} with $j_n \cap j_{n-1} \neq \emptyset$; in particular, the above containment holds if $j_n \cap j_{n-1} \neq \emptyset$.

Finally, the reader is urged to first read the following proof assuming that Y is a 2-manifold; once one understands the proof for this case it is an easy matter to understand the general case.

PROOF OF PROPOSITION (6.1). Let $\{\mathcal{G}_i\}_{i=1}^\infty$ be a sequence of f -admissible closed brick partitions of Y with $\mathcal{G}_i$ refining $\mathcal{G}_{i-1}$ and with $\lim_{i \rightarrow \infty} \mu(\mathcal{G}_i) = 0$. Let c_1 be such that $\mu(\mathcal{G}_{c_1}) < \varepsilon/3$; let $J_1 = \mathcal{G}_{c_1}$ and let $H_1 = f$. Let us assume that the metric on M is such that (6.1.4)¹ holds; this completes the $n = 1$ stage.

In (6.2)–(6.7), we give in detail the construction of the $n = 2$ stage; in (6.8) we indicate that the inductive step, going from the n th stage to the $(n + 1)$ st stage, can be done by modifying the construction of the $n = 2$ stage. In (6.3)_s, (the subscript s will be explained later) we carefully construct several collections of arcs and in (6.5) and (6.6) we modify H_1 by “pulling” various sets over these arcs in order to obtain H_2 (recall the proof of Proposition (4.2)).

(6.2) Let $\delta = 1/2^2$ and let $a_2 > c_1$ be such that:

(6.2.1) $\mu(\mathcal{G}_{a_2}) < \xi_2/2^2$ and for each $g \in \mathcal{G}_{a_2}$, $\cap \{j_1 \in J_1 \mid j_1 \text{ meets } \text{st}^2(g, \mathcal{G}_{a_2})^*\} \neq \emptyset$. The partition $\mathcal{G}_{a_2}$ is used to control the construction so that condition (6.1.3)² will hold.

Let $\mathcal{Q}, \mathfrak{N}_1, \dots, \mathfrak{N}_{I(\mathcal{Q})}$ be the filtration obtained from the brick partition $J_1 = \{j_1^1, \dots, j_1^T\}$ (see §2). We are now going to build J_2 inductively, $s = 1, \dots, I(\mathcal{Q})$, using the $\mathfrak{N}_s$'s; at the same time we will be constructing collections of arcs which will be used later to modify H_1 in order to obtain H_2 (we emphasize that *no modifying* of H_1 is done until (6.5)). The subscript s in (6.3)_s refers to the s th stage in the induction, $s = 1, \dots, I(\mathcal{Q})$.

(6.3)₁ The $s = 1$ stage: Let $3\tau_1 = \min\{d(|x|, Y - j_1^{u_1} \cup \dots \cup j_1^{u_k}) \mid x = (u_1, \dots, u_k) \in \mathfrak{N}_1\}$; recall that if $x, y \in \mathfrak{N}_1$ and $x \neq y$, then $|x| \cap |y| = \emptyset$. Let $c_2^1 > a_2$ be such that:

(6.3.1)₁ $\mu(\mathcal{G}_1) < \tau_1$ and for each $x \in \mathfrak{N}_1$, letting $J_2^x = \text{st}(|x|, \mathcal{G}_{c_2^1})$, $(J_2^x)^* \subseteq \text{int}(\text{st}(|x|, \mathcal{G}_{a_2})^*)$.

Let $J_2^1 = \{J_2^x \mid x \in \mathfrak{N}_1\}^*$; J_2^1 will be a subset of J_2 .

Let $\Gamma_1 = \{(j_2, u) \mid \text{for some } x \in \mathfrak{N}_1, j_2 \in J_2^x \text{ and } u \text{ appears in } x; \text{ i.e., } j_2 \cap j_2^u \neq \emptyset\}$. For each $\gamma = (j_2, u) \in \Gamma_1$, let $Q_\gamma \subseteq H_1^{-1}(\text{int}(j_2))$ be an open m -ball with $\text{diam}(Q_\gamma) < \delta/4$ and let

$$\eta_\gamma = \eta_\gamma^1 \cup \dots \cup \eta_\gamma^{b_\gamma} \subseteq H_1^{-1}(\text{int}(j_2 \cup j_1^u))$$

be an arc satisfying:

(6.3.4)₁ $\eta_\gamma^1 \subseteq Q_\gamma$; $\eta_\gamma^i(1) \in H_1^{-1}(\text{int}(j_1^u)) \subseteq N_{\delta/2}(\eta_\gamma)$; for $i = 1, \dots, b_\gamma$, $\text{diam}(\eta_\gamma^i) < \delta/4$.

In addition, we assume that the $\eta_\gamma \cup \bar{Q}_\gamma$'s are pairwise disjoint. Let $E_1 = \max\{b_\gamma | \gamma \in \Gamma_1\}$ and let $\mathcal{E}_1 = E_1 + 1$; for each $j_2 \in J_2^1$, let

$$\mathcal{P}_{j_2} = \{Q_\gamma | \gamma \in \Gamma_1 \text{ and } Q_\gamma \subseteq H_1^{-1}(\text{int}(j_2)); \text{ i.e., } \gamma = (j_2, u)\}.$$

(6.3)_s The inductive step, $s = 2, \dots, I(\mathcal{Q})$: For each $x = (u_1, \dots, u_k) \in \mathcal{N}_s$, let

$$|\hat{x}| = \text{cl}(|x| - (J_2^1 \cup \dots \cup J_2^{s-1})^*)$$

and let

$$D^x = (Y - j_1^{u_1} \cup \dots \cup j_1^{u_k}) \\ \cup \{(J_i^y)^* | y \in \mathcal{N}_1 \cup \dots \cup \mathcal{N}_{s-1} \text{ and } y \preccurlyeq x\}^*.$$

Let $3\tau_s = \min\{d(|\hat{x}|, D^x) | x \in \mathcal{N}_s\}$ and let $c_2^s > c_2^{s-1}$ be such that:

(6.3.1)_s $\mu(\mathcal{G}_{c_2^s}) < \tau_s$ and, for $x \in \mathcal{N}_s$, letting

$$J_2^x = \text{st}(|\hat{x}|, \mathcal{G}_{c_2^s}) - \text{st}^0((J_2^1 \cup \dots \cup J_2^{s-1})^*, \mathcal{G}_{c_2^s}),$$

$(J_2^x)^* \subseteq \text{int}(\text{st}(|\hat{x}|, \mathcal{G}_{a_2})^*)$.

(6.3.2)_s For each $y \in \mathcal{N}_1 \cup \dots \cup \mathcal{N}_{s-1}$,

$$\text{st}^{\mathcal{E}_s-1}((J_2^y)^*, \mathcal{G}_{c_2^s})^* \subseteq \text{int}(\text{st}(|\hat{y}|, \mathcal{G}_{a_2})^*).$$

(6.3.3)_s Letting $J_2^s = \{J_2^x | x \in \mathcal{N}_s\}^*$, for each $j_2 \in J_2^s$, $\cap \{j_2' \in J_2^1 \cup \dots \cup J_2^{s-1} | j_2' \text{ meets } \text{st}^{\mathcal{E}_s-1}(j_2, \mathcal{G}_{c_2^s})^* \} \neq \emptyset$.

Let $\Gamma_s = \{(j_2, u) | \text{ for some } x \in \mathcal{N}_s, j_2 \in J_2^x \text{ and } u \text{ appears in } x; \text{ i.e., } j_2 \cap j_1^u \neq \emptyset\}$. For each $\gamma = (j_2, u) \in \Gamma_s$, let $Q_\gamma \subseteq H_1^{-1}(\text{int}(j_2))$ be an open m ball with $\text{diam}(Q_\gamma) < \delta/4$ and let

$$\eta_\gamma = \eta_\gamma^1 \cup \dots \cup \eta_\gamma^{b_\gamma} \subseteq H_1^{-1}(\text{int}(j_2 \cup j_1^u))$$

be an arc satisfying:

(6.3.4)_s $\eta_\gamma^1 \subseteq Q_\gamma$; $\eta_\gamma^i(1) \in H_1^{-1}(\text{int}(j_1^u)) \subseteq N_{\delta/2}(\eta_\gamma)$; for $i = 1, \dots, b_\gamma$, $\text{diam}(\eta_\gamma^i) < \delta/4$.

For each $j_2 \in J_2^1 \cup \dots \cup J_2^{s-1}$, define

$$\Omega_{j_2}^s = \Omega_{j_2}^{s,1} \cup \Omega_{j_2}^{s,2} \cup \dots \cup \Omega_{j_2}^{s,\mathcal{E}_s-1}$$

as follows:

$$\Omega_{j_2}^{s,1} = \{\text{chains}(j_2^1) | j_2^1 \in J_2^s \text{ and } j_2 \cap j_2^1 \neq \emptyset\};$$

$$\Omega_{j_2}^{s,2} = \{\text{chains}(j_2^1, j_2^2) | j_2^1, j_2^2 \in J_2^s \text{ and } j_2 \cap j_2^1 \neq \emptyset\}; \dots;$$

$$\Omega_{j_2}^{s,\mathcal{E}_s-1} = \{\text{chains}(j_2^1, j_2^2, \dots, j_2^{\mathcal{E}_s-1}) | j_2^1, j_2^2, \dots, j_2^{\mathcal{E}_s-1} \in J_2^s \text{ and } j_2 \cap j_2^1 \neq \emptyset\}.$$

Let $j_2 \in J_2^1 \cup \dots \cup J_2^{s-1}$. For each $\omega_1 = (j_2^1) \in \Omega_{j_2}^{s,1}$ and for each $p \in \mathcal{P}_{j_2}$, let

$$\Sigma_{\omega_1, p}^s = (Q_{\omega_1, p}, \alpha_{\omega_1, p} = \alpha_{\omega_1, p}^1 \cup \dots \cup \alpha_{\omega_1, p}^{d_{\omega_1, p}})$$

be such that:

(6.3.5) $_s^{\omega_1, p}$ $Q_{\omega_1, p} \subseteq H_1^{-1}(\text{int}(j_2^1))$ is an open m ball with $\text{diam}(Q_{\omega_1, p}) < \delta/4$; $\alpha_{\omega_1, p} \subseteq H_1^{-1}(\text{int}(j_2 \cup j_2^1))$ is an arc with $\alpha_{\omega_1, p}^1 \subseteq Q_{\omega_1, p}$, with $\alpha_{\omega_1, p}(1) \in p$, and with $\text{diam}(\alpha_{\omega_1, p}^k) < \delta/4$ for $1 \leq k \leq d_{\omega_1, p}$.

Inductively, $i = 2, \dots, \mathfrak{E}_{s-1}$, for each $\omega_i = (j_2^1, \dots, j_2^i) \in \Omega_{j_2}^{s, i}$ and for each $p \in \mathcal{P}_{j_2}$, let

$$\Sigma_{\omega_i, p}^s = (Q_{\omega_i, p}, \alpha_{\omega_i, p} = \alpha_{\omega_i, p}^1 \cup \dots \cup \alpha_{\omega_i, p}^{d_{\omega_i, p}})$$

be such that:

(6.3.5) $_s^{\omega_i, p}$ $Q_{\omega_i, p} \subseteq H_1^{-1}(\text{int}(j_2^i))$ is an open m ball with $\text{diam}(Q_{\omega_i, p}) < \delta/4$; $\alpha_{\omega_i, p} \subseteq H_1^{-1}(\text{int}(j_2^{i-1} \cup j_2^i))$ is an arc with $\alpha_{\omega_i, p}^1 \subseteq Q_{\omega_i, p}$, with $\alpha_{\omega_i, p}(1) \in Q_{\omega_{i-1}, p}$ where $\omega_{i-1} = (j_2^1, \dots, j_2^{i-1})$, and with $\text{diam}(\alpha_{\omega_i, p}^k) < \delta/4$ for $k = 1, \dots, d_{\omega_i, p}$.

Let $E_s = \max\{\{b_\gamma | \gamma \in \Gamma_s\} \cup \{d_{\omega, p} | j_2 \in J_2^1 \cup \dots \cup J_2^{s-1}, \omega \in \Omega_{j_2}^s, \text{ and } p \in \mathcal{P}_{j_2}\}\}$ and let $\mathfrak{E}_s = 1 + \mathfrak{E}_1 + \mathfrak{E}_1 \cdot E_2 + \dots + \mathfrak{E}_{s-1} \cdot E_s$. For each $j_2 \in J_2^s$, let $\mathcal{P}_{j_2} = \{Q_\gamma | \gamma \in \Gamma_s \text{ and } Q_\gamma \subseteq H_1^{-1}(\text{int}(j_2))\}$; i.e., $\gamma = (j_2, u) \cup \{Q_{\omega, p} | \omega = (j_2^1, \dots, j_2^s) \in \Omega_{j_2}^s, p \in \mathcal{P}_{j_2}, \text{ and } j_2 = j_2^s\}$; i.e., $Q_{\omega, p} \subseteq H_1^{-1}(\text{int}(j_2))$. This completes the induction on s .

(6.4) Let $J_2 = J_2^1 \cup \dots \cup J_2^{I(\mathcal{Q})}$. A final condition on the choices of arcs and m -balls in (6.3) $_1 - (6.3)_{I(\mathcal{Q})}$ is that there be no unnecessary intersections. More specifically: (i) all arcs constructed are to be pairwise disjoint; (ii) all the m -balls specified are to have pairwise disjoint closures; (iii) the only intersections between arcs and m balls are those necessitated by (6.3.4) $_s$ and (6.3.5) $_s$ for $s = 1, \dots, I(\mathcal{Q})$.

(6.5) The mapping H_2 will be obtained from H_1 by a finite number of alterations; we will now give a detailed description of one of these alterations.

Let $j_1^u \in J_1$ and let $j_2 \in \text{st}(j_1^u, J_2)$; let v_0 be such that $j_2 \in J_2^{v_0}$. Note that $\gamma = (j_2, u) \in \Gamma_{v_0}$. For $l = 1, \dots, t$ let v_l be an integer and let $(j_2^{1_l}, \dots, j_2^{r_l})$ be a chain such that:

(6.5.1) $1 \leq v_0 \leq v_1 \leq \dots \leq v_t \leq I(\mathcal{Q})$; $(j_2^{1_l}, \dots, j_2^{r_l}) \in \Omega_{j_2}^{v_l}$; and, for $l = 2, \dots, t$,

$$(j_2^{1_l}, \dots, j_2^{r_l}) \in \Omega_{j_2^{r_{l-1}}}^{v_l}.$$

In particular, $(j_2, j_2^{1_1}, \dots, j_2^{r_1}, \dots, j_2^{1_t}, \dots, j_2^{r_t})$ is a chain.

For $l = 1, \dots, t$ and $i = 1, \dots, r_l$, let $\omega_i^l = (j_2^{1_l}, \dots, j_2^{r_l})$; from the data in (6.5.1) we obtain the following.

(6.5.2) $R_0 = \{(Q_\gamma, \eta_\gamma = \eta_\gamma^1 \cup \dots \cup \eta_\gamma^{b_\gamma})\}$ where $\gamma = (j_2, u)$; letting $p_1 = Q_\gamma$,

$$R_1 = \{\Sigma_{\omega_1^1, p_1}^{v_1} = (Q_{\omega_1^1, p_1}, \alpha_{\omega_1^1, p_1} = \alpha_{\omega_1^1, p_1}^1 \cup \dots \cup \alpha_{\omega_1^1, p_1}^{d_{\omega_1^1, p_1}}), \dots,$$

$$\Sigma_{\omega_{r_1}^1, p_1}^{v_1} = (Q_{\omega_{r_1}^1, p_1}, \alpha_{\omega_{r_1}^1, p_1} = \alpha_{\omega_{r_1}^1, p_1}^1 \cup \dots \cup \alpha_{\omega_{r_1}^1, p_1}^{d_{\omega_{r_1}^1, p_1}})\};$$

for $l = 2, \dots, t$, letting $p_l = Q_{\omega_{l-1}^{l-1}, p_{l-1}}$,

$$R_l = \left\{ \Sigma_{\omega_{l-1}^{l-1}, p_l}^{v_l} = \left(Q_{\omega_{l-1}^{l-1}, p_{l-1}}, \alpha_{\omega_{l-1}^{l-1}, p_l} = \alpha_{\omega_{l-1}^{l-1}, p_l}^1 \cup \dots \cup \alpha_{\omega_{l-1}^{l-1}, p_l}^{d_{\omega_{l-1}^{l-1}, p_l}} \right), \dots, \right. \\ \left. \Sigma_{\omega_{l-1}^{l-1}, p_l}^{v_l} = \left(Q_{\omega_{l-1}^{l-1}, p_l}, \alpha_{\omega_{l-1}^{l-1}, p_l} = \alpha_{\omega_{l-1}^{l-1}, p_l}^1 \cup \dots \cup \alpha_{\omega_{l-1}^{l-1}, p_l}^{d_{\omega_{l-1}^{l-1}, p_l}} \right) \right\}.$$

$N(\eta_\gamma)$ and $N(\alpha_{\omega, p})$ will denote "small" neighborhoods of the arcs η_γ and $\alpha_{\omega, p}$, respectively. Since all the arcs involved are pairwise disjoint, we can assume that all such neighborhoods are pairwise disjoint; in addition, if $\gamma = (j_2, u)$; then $N(\eta_\gamma) \subseteq H_1^{-1}(\text{int}(j_2 \cup j_1''))$ and if $\omega = (j_2^1, \dots, j_2^r) \in \Omega_{j_2}^r$, then $N(\alpha_{\omega, p}) \subseteq H_1^{-1}(\text{int}(j_2 \cup j_2^1))$ when $r = 1$ and $N(\alpha_{\omega, p}) \subseteq H_1^{-1}(\text{int}(j_2'^{-1} \cup j_2'))$ when $r \neq 1$. Furthermore, at various points during the altering of H_1 and the verifying that J_2 and H_2 satisfy (6.1.1)²–(6.1.5)² we will further restrict the size of these neighborhoods.

Before describing the alteration, it is convenient to simplify the notation describing the data in (6.5.2). Let

$$(\beta_0, \beta_1, \dots, \beta_D) \\ = (\eta_\gamma, \alpha_{\omega_1, p_1}, \dots, \alpha_{\omega_1, p_1}, \alpha_{\omega_2, p_2}, \dots, \alpha_{\omega_2, p_2}, \dots, \alpha_{\omega_t, p_t}, \dots, \alpha_{\omega_t, p_t});$$

let $Q_{\beta_0} = Q_\gamma$, and for $\beta_{i'} = \alpha_{\omega_{i'}, p_{i'}}$ let $Q_{\beta_{i'}} = Q_{\omega_{i'}, p_{i'}}$. The arc β_0 is the union of η_γ 's and each of $\beta_1, \beta_2, \dots, \beta_D$ is the union of $\alpha_{\omega, p}$'s; let $\lambda_1, \lambda_2, \dots, \lambda_B$ be the collection of these subarcs of the β_i 's ordered as follows:

$$\beta_D = \lambda_1 \cup \lambda_2 \cup \dots \cup \lambda_{q_D}, \\ \beta_{D-1} = \lambda_{q_D+1} \cup \lambda_{q_D+2} \cup \dots \cup \lambda_{q_{D-1}}, \dots, \\ \beta_1 = \lambda_{q_2+1} \cup \dots \cup \lambda_{q_1}, \\ \beta_0 = \lambda_{q_1+1} \cup \dots \cup \lambda_B.$$

Using the above data alter H_1 as follows. Let $\{h_t\}_{t \in [0, 1]}$ be an isotopy of M with $h_0 = \text{identity}$ and with $\text{supp}(\{h_t\}_{t \in [0, 1]}) \subseteq N(\beta_0)$ such that $\{h_t^{-1}\}_{t \in [0, 1]}$ "pulls" a small neighborhood of $\beta_0(0)$ contained in Q_{β_0} over the entire arc β_0 . Successively, $i = 1, \dots, D$, let $\{h_t\}_{t \in [2i, 2i+1]}$ be an isotopy of M with $h_{2i} = \text{identity}$ and with

$$\text{supp}(\{h_t\}_{t \in [2i, 2i+1]}) \subseteq N(\beta_i) \cup \left(\bigcup_{q=0}^{i-1} (Q_{\beta_q} \cup N(\beta_q)) \right)$$

such that $\{h_t^{-1}\}_{t \in [2i, 2i+1]}$ "pulls" a small neighborhood of $\beta_i(0)$ contained in Q_{β_i} over the entire arc β_i and then "pulls" the neighborhood "alongside" $\lambda_{\beta_i} \cup \lambda_{\beta_{i+1}} \cup \dots \cup \lambda_{\beta_{D-1}}$. Let $\hat{H}_1 = H_1 \circ h_{2D+1} \circ h_{2(D-1)+1} \circ \dots \circ h_1$.

Essentially, H_2 is obtained from H_1 by making the above alteration for all possible choices of data satisfying (6.5.1) and (6.5.2); however, there is the minor problem that different sets of data may well "overlap". More precisely,

two sets of data $(\beta_0, \dots, \beta_D)$ and $(\beta'_0, \dots, \beta'_D)$ are said to *overlap* provided that there are q and q' with $\beta_q = \beta'_{q'}$; in this case, it follows that $\beta_{q+1} = \beta'_{q'+1}$, $\beta_{q+2} = \beta'_{q'+2}, \dots, \beta_D = \beta'_D$. (This last statement can be verified using the following two facts. First, if $\beta_q = \beta'_{q'}$, then either $q = q' = 0$ and $\beta_q = \beta'_{q'} = \eta_\gamma$ or

$$\beta_q = \alpha_{\omega_i^k, p_k}, \quad \beta'_{q'} = \alpha_{\omega_{i'}^{k'}, p'_{k'}}$$

and, therefore, $\omega_i^k = \omega_{i'}^{k'}$ and $p_k = p'_{k'}$. Second, ω_i^k (resp., $\omega_{i'}^{k'}$) and the conditions in (6.5.2) that $p_1 = Q_\gamma$ (resp., $p'_1 = Q'_{\gamma'}$) and, for $l = 2, \dots, t$, $p_l = Q_{\omega_{i-1}^{l-1}, p_{l-1}}$ (resp., $l = 2, \dots, t'$, $p'_l = Q'_{\omega_{i'-1}^{l'-1}, p'_{l-1}}$) completely determine $\beta_{q+1}, \dots, \beta_D$ (resp., $\beta'_{q'+1}, \dots, \beta'_D$).

The alterations described above have two important features. First each set “pulled alongside” various arcs meets only that arc which it is “pulled over”. Second, the sets “pulled alongside” various arcs are “pulled straight alongside” the arcs; i.e., the sets are *not* permitted to “wiggle back and forth” along the arcs. (The second feature and the facts that the $\text{diam}(Q_\beta)$ ’s are less than $\delta/4$ and that the $\text{diam}(\lambda_i)$ ’s are less than $\delta/4$ imply that each successive set “pulled” alongside the λ_i ’s is within $\delta/2$ of the previous one. At least this will be the case if the $N(\beta_i)$ ’s are chosen small enough; we assume that they have been so chosen.)

One way of obtaining H_2 is to make the indicated alteration for all possible choices of data in (6.5.1) and (6.5.2). The reader should observe that conditions (6.1.2)² and (6.1.5)² can be verified by studying the role of the η_γ ’s. Condition (6.1.3)² is relatively easy to verify but it is convenient to delay doing so until later. We are left with condition (6.1.4)²; certainly, achieving (6.1.4)² is the central difficulty faced throughout the construction. At this point, we suggest that the reader compare condition (6.1.4)² and the alterations outlined in this section in order to get a “sense” that (6.1.4)² holds.

Thus far we have attempted to give a global description H_2 ; in the next section, we will obtain H_2 from H_1 in a more “controlled” manner thereby facilitating the verification of condition (6.1.4)². The method of the next section will also illuminate the role of the filtration $\mathfrak{N}_1, \dots, \mathfrak{N}_{I(\mathcal{Q})}$.

(6.6) We are now going to alter H_1 inductively for $s = 1, \dots, I(\mathcal{Q})$. Recall that the $N(\eta_\gamma)$ ’s and the $N(\alpha_{\omega, p})$ ’s are small neighborhoods of the η_γ ’s and $\alpha_{\omega, p}$ ’s, respectively.

$s = 1$: For each $\gamma = (j_2, u) \in \Gamma_1$, alter H_1 by using an isotopy of M with support contained in $Q_\gamma \cup N(\eta_\gamma)$ to “pull” a small neighborhood of $\eta_\gamma(0)$ contained in Q_γ over the entire arc η_γ . Let $H_{1,1}$ denote the mapping so obtained. It is easily verified that $H_{1,1}$ satisfies (6.1.2)² and (6.1.5)² for $j_2 \in J_2^1$. We now check that $H_{1,1}$ satisfies (6.1.4)² for pairs $j_2, j'_2 \in J_2^1$ with $j_2 \cap j'_2 \neq \emptyset$. Let $x = (u_1, \dots, u_k) \in \mathfrak{N}_1$ with $j_2, j'_2 \in J_2^x$; then we have that

$$H_{1,1}^{-1}(\text{int}(j_2)) \subseteq H_1^{-1}(\text{int}(j_1^{u_1} \cup \dots \cup j_1^{u_k})) \subseteq N_\delta(H_{1,1}^{-1}(\text{int}(j'_2))).$$

(The latter containment follows from (6.1.5)² and the fact that J_1 is H_1 -admissible.)

$s = 2$: For each $\gamma = (j_2, u) \in \Gamma_2$, alter $H_{1,1}$ by using an isotopy of M with support contained in $Q_\gamma \cup N(\eta_\gamma)$ to "pull" a small neighborhood of $\eta_\gamma(0)$ contained in Q_γ over the entire arc η_γ . Let $H'_{1,2}$ denote the mapping so obtained. It is easily verified that $H'_{1,2}$ satisfies (6.1.2)² and (6.1.5)² for $j_2 \in J_2^1 \cup J_2^2$; however, $H'_{1,2}$ does not satisfy (6.1.4)² for all pairs $j_2, j'_2 \in J_2^1 \cup J_2^2$ with $j_2 \cap j'_2 \neq \emptyset$ ($H'_{1,2}$ does satisfy (6.1.4)² for such pairs $j_2, j'_2 \in J_2^1$).

Let $\omega = (j_2^1, \dots, j_2^l) \in \Omega_{j_2}^2$ for some $j_2 \in J_2^1$ and let $p \in \mathcal{P}_{j_2}$; necessarily, $p = Q_\gamma$ for some $\gamma = (j_2, u) \in \Gamma_1$. Obtain a set of data as in (6.5.1) by letting $v_0 = 1, v_1 = 2$ ($l = 1$), and $(j_2^{1,1}, \dots, j_2^{l,1}) = \omega$. Extract the data of (6.5.2) from the above data and alter $H'_{1,2}$ as outlined in (6.5); observe that part of the alteration was done while altering H_1 to get $H_{1,1}$. The mapping $H_{1,2}$ is obtained by making the above alteration for all triples $j_2 \in J_2^1, \omega \in \Omega_{j_2}^2$, and $p \in \mathcal{P}_{j_2}$ (if the present data j_2, ω, p overlaps with previous data j'_2, ω', p , then part or all of the alteration based on j_2, ω, p will have been done; in that case, complete the remainder of the alteration).

Certainly, $H_{1,2}$ satisfies (6.1.2)² and (6.1.5)² for $j_2 \in J_2^1 \cup J_2^2$ and there is no difficulty in doing the above altering of $H'_{1,2}$ so that $H_{1,2}$ satisfies (6.1.4)² for $j_2, j'_2 \in J_2^1$. That (6.1.4)² holds for pairs $j_2, j'_2 \in J_2^1 \cup J_2^2$ can be checked as follows.

Case 1. $j_2 \in J_2^2$ and $j'_2 \in J_2^1$ with $j_2 \cap j'_2 \neq \emptyset$.

Let $y \in \mathfrak{M}_1$ with $j'_2 \in J_2^1$ and let $x \in \mathfrak{M}_2$ with $j_2 \in J_2^2$. Let $x = (u_1, \dots, u_k)$ and $y = (u'_1, \dots, u'_k)$; it follows from (6.3.1)₂ that $x \succ y$ and, therefore, that $\{u_1, \dots, u_k\} \subseteq \{u'_1, \dots, u'_k\}$.

We first show that

$$H_{1,2}^{-1}(\text{int}(j_2)) \subseteq N_\delta(H_{1,2}^{-1}(\text{int}(j'_2)));$$

since $H_1^{-1}(\text{int}(j_1^{u_1} \cup \dots \cup j_1^{u_k})) \subseteq N_{\delta/2}(H_{1,2}^{-1}(\text{int}(j'_2)))$, it suffices to show that

$$H_{1,2}^{-1}(\text{int}(j_2)) \subseteq H_1^{-1}(\text{int}(j_1^{u_1} \cup \dots \cup j_1^{u_k})).$$

Since a chain in any $\Omega_{j_2}^2$ has length at most $\mathfrak{S}_1$, it follows from (6.3.3)₂ that if j_2 appears in a chain $\omega \in \Omega_{j_2}^2$ and $\gamma = (j_2'', u'') \in \Gamma_1$, then $u'' \in \{u'_1, \dots, u'_k\}$. The containment $H_{1,2}^{-1}(\text{int}(j_2)) \subseteq H_1^{-1}(\text{int}(j_1^{u_1} \cup \dots \cup j_1^{u_k}))$ follows by observing the effect of the various alterations on $H_1^{-1}(\text{int}(j_2))$.

We now show that

$$H_{1,2}^{-1}(\text{int}(j'_2)) \subseteq N_\delta(H_{1,2}^{-1}(\text{int}(j_2))).$$

Since $H_{1,2}^{-1}(\text{int}(j'_2)) \subseteq H_1^{-1}(\text{int}(j_1^{u'_1} \cup \dots \cup j_1^{u'_k}))$, it is enough to show that

$$H_{1,2}^{-1}(\text{int}(j'_2)) \cap H_1^{-1}(\text{int}(j_i^u)) \subseteq N_{\delta/2}(H_{1,2}^{-1}(\text{int}(j_2))) \quad \text{for } i = 1, \dots, k'.$$

The latter containment is true for $u_i' \in \{u_1, \dots, u_k\}$ since for such u_i' we have that $H_1^{-1}(\text{int}(j_i^u)) \subseteq N_{\delta/2}(H_{1,2}^{-1}(\text{int}(j_2)))$. If $u_i' \notin \{u_1, \dots, u_k\}$, then $j'_2 \not\subseteq j_1^u$; therefore, $H_{1,2}^{-1}(\text{int}(j'_2)) \cap H_1^{-1}(\text{int}(j_1^u))$ is determined by the fact that H_1 was altered by pulling $H_1^{-1}(\text{int}(j'_2))$ over η_γ for $\gamma = (j'_2, u_i')$. Let $\omega = (j_2) \in \Omega_{j'_2}^2$ and let $p = Q_\gamma$ ($\gamma = (j'_2, u_i')$); $H'_{1,2}$ was modified with respect to the data j'_2 , ω , and p and this modification guarantees that $H_{1,2}^{-1}(\text{int}(j'_2)) \cap H_1^{-1}(\text{int}(j_1^u)) \subseteq N_{\delta/2}(H_{1,2}^{-1}(\text{int}(j_2)))$. (At least the last statement is true if the neighborhood $N(\eta_\gamma)$ is "small enough".)

Case 2. $j_2, j'_2 \in J_2^2$ with $j_2 \cap j'_2 \neq \emptyset$.

Since the roles of j_2 and j'_2 are interchangeable, it suffices to show that $H_{1,2}^{-1}(\text{int}(j_2)) \subseteq N_\delta(H_{1,2}^{-1}(\text{int}(j'_2)))$. First, observe that (6.3.1)₂ implies that there is a unique $\gamma = (u_1, \dots, u_k) \in \mathfrak{M}_2$ with $j_2, j'_2 \in J_2^\gamma$. For $i = 1, \dots, k$, we have that

$$H_{1,2}^{-1}(\text{int}(j_2)) \cap H_1^{-1}(\text{int}(j_1^u)) \subseteq H_1^{-1}(\text{int}(j_1^u)) \subseteq N_{\delta/2}(H_{1,2}^{-1}(\text{int}(j'_2))).$$

We must show that if $u \notin \{u_1, \dots, u_k\}$ and $H_{1,2}^{-1}(\text{int}(j_2)) \cap H_1^{-1}(\text{int}(j_1^u)) \neq \emptyset$, then the intersection is contained in $N_{\delta/2}(H_{1,2}^{-1}(\text{int}(j'_2)))$. This intersection is determined by choices of data $j''_2 \in J_2^1$, $\omega = (j_2^1, \dots, j'_2) \in \Omega_{j'_2}^2$, and $p \in \mathcal{P}_{j'_2}$ with $j''_2 \in \text{st}(j_1^u, J_2^1)$ and $j'_2 = j_2$. (Recall from the definition of $\Omega_{j'_2}^2$ that $r \leq \delta_1$.) If $r = \delta_1$, then the alteration based on the data j''_2 , ω , and p does *not* result in $H_{1,2}^{-1}(\text{int}(j_2))$ meeting $H_1^{-1}(\text{int}(j_1^u))$; this is true in view of the definition of δ_1 and in view of the feature in the alteration which has $H_{1,2}^{-1}(\text{int}(j_2))$ being "pulled less and less far" into $H_1^{-1}(\text{int}(j_1^u))$ as i gets larger. If $r < \delta_1$ and $j'_2 \notin \{j_2^1, \dots, j_2^{r-1}\}$, then the data $j''_2, \hat{\omega}(j_2^1, \dots, j_2^{r-1}, j'_2) \in \Omega_{j'_2}^2$, and $\hat{p} \in \mathcal{P}_{j'_2}$ will result in $H_{1,2}^{-1}(\text{int}(j'_2))$ being "pulled" to within $\delta/2$ of that part of $H_{1,2}^{-1}(\text{int}(j_2)) \cap H_1^{-1}(\text{int}(j_1^u))$ resulting from the alteration done with respect to the data j''_2 , ω , and p . If $r < \delta_1$ and $j'_2 = j_2^t$ for some $1 < t < r - 1$, then that part of $H_{1,2}^{-1}(\text{int}(j_2))$ "pulled" into $H_1^{-1}(\text{int}(j_1^u))$ (by the alteration based on the data j''_2 , ω , and p) was "pulled inside" that part of $H_{1,2}^{-1}(\text{int}(j'_2))$ "pulled" into $H_1^{-1}(\text{int}(j_1^u))$ (by the alteration based on the data $j''_2, (j_2^1, \dots, j_2^t) \in \Omega_{j'_2}^2$, and p). Combining the above two statements, we have that

$$H_{1,2}^{-1}(\text{int}(j_2)) \cap H_1^{-1}(\text{int}(j_1^u)) \subseteq N_{\delta/2}(H_{1,2}^{-1}(\text{int}(j'_2))).$$

The inductive step, altering $H_{1,s}$ to get $H_{1,s+1}$: For each $\gamma \in \Gamma_{s+1}$, alter $H_{1,s}$ with respect to η_γ exactly as $H_{1,1}$ was altered to get $H'_{1,2}$; let $H'_{1,s+1}$ denote the mapping so obtained. Part of the inductive hypothesis (we have *not* explicitly displayed the inductive hypothesis) is that $H_{1,s}$ satisfies (6.1.2)² and (6.1.5)² for $j_2 \in J_2^1 \cup \dots \cup J_2^s$. It is easily verified that $H'_{1,s+1}$ satisfies (6.1.2)² and (6.1.5)² for $j_2 \in J_2^1 \cup \dots \cup J_2^{s+1}$; however, $H'_{1,s+1}$ *does not* satisfy (6.1.4)²

for all pairs $j_2, j'_2 \in J_2^1 \cup \dots \cup J_2^{s+1}$ with $j_2 \cap j'_2 \neq \emptyset$. (Part of the inductive hypothesis is that $H_{1,s}$ satisfies (6.1.4)² for all pairs $j_2, j'_2 \in J_2^1 \cup \dots \cup J_2^s$ with $j_2 \cap j'_2 \neq \emptyset$; it follows easily that $H'_{1,s+1}$ satisfies (6.1.4)² for such pairs.)

Let $\omega = (j_2^1, \dots, j_2^t) \in \Omega_{j_2}^{s+1}$ for some $j_2 \in J_2^1 \cup \dots \cup J_2^s$ and let $p \in \mathcal{P}_{j_2}$. If $p = Q_\gamma$ for some $\gamma \in \Gamma_1 \cup \dots \cup \Gamma_s$, then obtain a set of data as in (6.5.1) by letting $v_0 = 1$, $v_1 = s + 1$ ($l = 1$), and $(j_2^1, \dots, j_2^t) = \omega$; extract the data of (6.5.2) from the above data and alter $H'_{1,s+1}$ as outlined in (6.5) (more precisely, complete that part of the alteration which has not been done previously). If $p = Q_{\omega'_2 p'_2}$ (it is convenient to let $\omega'_1 = \omega$, $p'_1 = p$, $v'_1 = s + 1$, and $j_{2,1} = j_2$), then integers $1 \leq v_0 < v_1 < \dots < v_t \leq I(\mathcal{Q})$, chains $(j_2^1, \dots, j_2^{t'})$ for $l = 1, \dots, t$, and an element $\gamma = (j'_2, u_k) \in \Gamma_{v_0}$ are uniquely determined as follows. Let v'_2 be such that $\omega'_2 \in \Omega_{j_{2,2}}^{v'_2}$ for some $j_{2,2} \in J_2^1 \cup \dots \cup J_2^{v'_2-1}$ (necessarily, $v'_2 \leq v'_1$). If $p'_2 = Q_{\omega'_3 p'_3}$, then let v'_3 be such that $\omega'_3 \in \Omega_{j_{2,3}}^{v'_3}$ for some $j_{2,3} \in J_2^1 \cup \dots \cup J_2^{v'_3-1}$ (necessarily, $v'_3 \leq v'_2$). If $p'_3 = Q_{\omega'_4 p'_4}$, then let v'_4 be such that $\omega'_4 \in \Omega_{j_{2,4}}^{v'_4}$ for some $j_{2,4} \in J_2^1 \cup \dots \cup J_2^{v'_4-1}$ (necessarily, $v'_4 \leq v'_3$). Continue in this manner until $p'_t = Q_{\omega'_{t+1} p'_{t+1}}$ and $p'_{t+1} = Q_\gamma$; let v'_{t+1} be such that $\gamma = (j'_2, u) \in \Gamma_{v'_{t+1}}$ (necessarily, $v'_{t+1} \leq v'_t$). Data as in (6.5.1) is obtained by letting $v_0 = v'_{t+1}$, $v_1 = v'_t$, $v_2 = v'_{t-1}$, $\dots$, $v_t = v'_1$ and letting $(j_2^1, \dots, j_2^t) = \omega'_{-t+1}$ for $l = 1, \dots, t$. Extract the data of (6.5.2) from the above data and alter $H'_{1,s+1}$ as outlined in (6.5) (more precisely, complete that part of the alteration which has not been done previously).

Let $H_{1,s+1}$ be the mapping obtained by making the above alteration for all triples $\omega \in \Omega_{j_2}^{s+1}$, $j_2 \in J_2^1 \cup \dots \cup J_2^s$, and $p \in \mathcal{P}_{j_2}$. Certainly, $H_{1,s+1}$ satisfies (6.1.2)² and (6.1.5)² for $j_2 \in J_2^1 \cup \dots \cup J_2^{s+1}$ and there is no difficulty in doing the above altering of $H'_{1,s+1}$ so that $H_{1,s+1}$ satisfies (6.1.4)² for $j_2, j'_2 \in J_2^1 \cup \dots \cup J_2^s$. That (6.1.4)² holds for pairs $j_2, j'_2 \in J_2^1 \cup \dots \cup J_2^{s+1}$ can be checked by checking the following cases.

Case 1.1. $j_2 \in J_2^{s+1}$ and $j'_2 \in J_2^1$ with $j_2 \cap j'_2 \neq \emptyset$.

Case 1.2. $j_2 \in J_2^{s+1}$ and $j'_2 \in J_2^2$ with $j_2 \cap j'_2 \neq \emptyset$.

⋮

Case 1.s. $j_2 \in J_2^{s+1}$ and $j'_2 \in J_2^s$ with $j_2 \cap j'_2 \neq \emptyset$.

Case 2. $j_2, j'_2 \in J_2^{s+1}$ with $j_2 \cap j'_2 \neq \emptyset$.

Checking Case 1.e for $1 \leq e \leq s$. Let $y \in \mathfrak{N}_e$ with $j'_2 \in J_2^e$ and let $x \in \mathfrak{N}_{s+1}$ with $j_2 \in J_2^x$. Let $x = (u_1, \dots, u_k)$ and $y = (u'_1, \dots, u'_k)$; it follows from (6.3.1)_{s+1} that $x \geq y$ and, therefore, that $\{u_1, \dots, u_k\} \subseteq \{u'_1, \dots, u'_k\}$.

$H_{1,s+1}^{-1}(\text{int}(j_2)) \subseteq N_\delta(H_{1,s+1}^{-1}(\text{int}(j'_2)))$. It suffices to show that if $H_{1,s+1}^{-1}(\text{int}(j_2)) \cap H_1^{-1}(\text{int}(j_1'')) \neq \emptyset$, then this intersection is contained in $N_{\delta/2}(H_{1,s+1}^{-1}(\text{int}(j'_2)))$. If $u \in \{u'_1, \dots, u'_k\}$, then the latter containment holds since $H_1^{-1}(\text{int}(j_1'')) \subseteq N_{\delta/2}(H_{1,s+1}^{-1}(\text{int}(j'_2)))$. For $u \notin \{u'_1, \dots, u'_k\}$, our approach is to show that if an alteration of $H_{1,s}$ resulted in $H_{1,s}^{-1}(\text{int}(j_2))$ being "pulled into" $H_1^{-1}(\text{int}(j_1''))$, then that part of $H_{1,s+1}^{-1}(\text{int}(j_2)) \cap H_1^{-1}(\text{int}(j_1''))$

resulting from the alteration is contained in $N_{\delta/2}(H_{1,s+1}^{-1}(\text{int}(j_2')))$.

The set $H_{1,s+1}^{-1}(\text{int}(j_2)) \cap H_1^{-1}(\text{int}(j_1''))$ is determined by alterations made with respect to sets of data consisting of integers $1 \leq v_0 \leq v_1 \leq \dots \leq v_t = s+1$, $\gamma = (j_2'', u'') \in \Gamma_{v_0}$, and chains $(j_2^{1'}, \dots, j_2^{t'})$ for $l = 1, \dots, t$ satisfying (6.5.1) such that j_2 appears in $(j_2^{1'}, \dots, j_2^{t'})$ and one or both of the following hold: (i) various of the $j_2^{l'}$'s are subsets of j_1'' ; (ii) $u'' = u$.

Let q be such that $1 \leq v_0 \leq v_1 \leq \dots \leq v_q \leq e \leq v_{q+1} \leq \dots \leq v_t$. Exploiting the fact that $u \notin \{u_1', \dots, u_{k'}'\}$ we will now show that $j_2' \cap j_2^{1'} \neq \emptyset$ and that if $j_2' \subseteq j_1''$, then $1 \leq l \leq q-1$. Condition (6.3.3) $_{v_i}$ implies that $j_2' \cap j_2^{l-1} \neq \emptyset$ (the reason being that both j_2' and j_2^{l-1} meet $\text{st}^{\mathcal{E}_{v_i-1}}(j_2, J_2^v)^*$ and $J_2^v \subseteq \mathcal{G}_{\mathcal{E}_i}^v$); $j_2' \cap j_2^{l-1} \neq \emptyset$ and condition (6.3.1) $_{v_{i-1}}$ imply that if $z \in \mathcal{M}_{v_{i-1}}$ with $j_2^{l-1} \in J_2^z$, then $z \geq y$; if $z' \in \mathcal{M}_{v_{i-1}}$ and $z' \neq z$, then (6.3.1) $_{v_{i-1}}$ implies that $(J_2^z)^* \cap (J_2^z)^* = \emptyset$ and, therefore,

$$\{j_2^{1'}, \dots, j_2^{v_{i-1}}\}^* \subseteq (J_2^z)^* \subseteq j_1^{u_1} \cup \dots \cup j_1^{u_k}.$$

We can use the argument in the preceding sentence to proceed inductively for $i = t-1, t-2, \dots, q+1$ as follows. Since $j_2' \cap j_2^{t'} \neq \emptyset$, condition (6.3.3) $_i$ implies that $j_2' \cap j_2^{t-1} \neq \emptyset$; condition (6.3.1) $_{v_{i-1}}$ and $j_2' \cap j_2^{t-1} \neq \emptyset$ imply that if $z \in \mathcal{M}_{v_{i-1}}$ with $j_2^{t-1} \in J_2^z$, then $z \geq y$; if $z' \in \mathcal{M}_{v_{i-1}}$ and $z' \neq z$, then (6.3.1) $_{v_{i-1}}$ implies that $(J_2^z)^* \cap (J_2^z)^* = \emptyset$ and, therefore,

$$\{j_2^{1'}, \dots, j_2^{v_{i-1}}\}^* \subseteq (J_2^z)^* \subseteq j_1^{u_1} \cup \dots \cup j_1^{u_k}.$$

If $v_q = e$ and $j_2' \in \{j_2^{1'}, \dots, j_2^{t'}\}$, then that part of $H_{1,s}^{-1}(\text{int}(j_2))$ being "pulled into" $H_1^{-1}(\text{int}(j_1''))$ by the alteration based on the data $\gamma = (j_2'', u'') \in \Gamma_{v_0}$ and $\{(j_2^{1'}, \dots, j_2^{t'})\}_{l=1, \dots, t}$ will be "pulled inside" of $H_{1,s}^{-1}(\text{int}(j_2)) \cap H_1^{-1}(\text{int}(j_1''))$ and, therefore, will be contained in $N_{\delta/2}(H_{1,s+1}^{-1}(\text{int}(j_2')))$.

If $v_q = e$, $j_2' \notin \{j_2^{1'}, \dots, j_2^{t'}\}$, and $r_q \leq \mathcal{E}_{v_q}$, then that part of $H_{1,s}^{-1}(\text{int}(j_2))$ being "pulled into" $H_1^{-1}(\text{int}(j_1''))$ based on the data $\gamma = (j_2'', u'') \in \Gamma_{v_0}$ and $\{(j_2^{1'}, \dots, j_2^{t'})\}_{l=1, \dots, t}$ will be "pulled alongside" that part of $H_{1,s}^{-1}(\text{int}(j_2))$ which was "pulled into" $H_1^{-1}(\text{int}(j_1''))$ by the previous alteration (done when altering H_{1,v_q-1} to get H_{1,v_q}) based on the data $\gamma = (j_2'', u'') \in \Gamma_{v_0}$ and $\{(j_2^{1'}, \dots, j_2^{t'})\}_{l=1, \dots, q-1} \cup \{(j_2^{1'}, \dots, j_2^{t'}, j_2)\}$. In particular, we will have the part of $H_{1,s+1}^{-1}(\text{int}(j_2)) \cap H_1^{-1}(\text{int}(j_1''))$ resulting from the above alteration contained in $N_{\delta/2}(H_{1,s+1}^{-1}(\text{int}(j_2')))$.

If $v_q = E$, $j_2' \notin \{j_2^{1'}, \dots, j_2^{t'}\}$, and $r_q = \mathcal{E}_{v_q}$, then the alteration based on the data $\gamma = (j_2'', u'') \in \Gamma_{v_0}$ and $\{(j_2^{1'}, \dots, j_2^{t'})\}_{l=1, \dots, t}$ will not result in $H_{1,s}^{-1}(\text{int}(j_2))$ being "pulled into" $H_1^{-1}(\text{int}(j_1''))$. (To see this, recall that none of the $j_2^{l'}$'s for $l = q, q+1, \dots, t$ are contained in j_1'' and, using the definition of $\mathcal{E}_{v_q}$, show that the part of $H_{1,s+1}^{-1}(\text{int}(j_2'))$ into which $H_{1,s}^{-1}(\text{int}(j_2))$ is being pulled does not meet $H_1^{-1}(\text{int}(j_1''))$.)

If $v_q \neq e$, then the part of $H_{1,s}^{-1}(\text{int}(j_2))$ being "pulled into" $H_1^{-1}(\text{int}(j_1''))$ based on the data $\gamma = (j_2'', u'') \in \Gamma_{v_0}$ and $\{(j_2^1, \dots, j_2^t)\}_{t=1, \dots, t}$ will be "pulled alongside" that part of $H_{1,s}^{-1}(\text{int}(j_2))$ which was "pulled into" $H_1^{-1}(\text{int}(j_1''))$ by the previous alteration (done when altering H_{1,v_q-1} to get H_{1,v_q}) based on the data $\gamma = (j_2'', u'') \in \Gamma_{v_0}$ and $\{(j_2^1, \dots, j_2^t) | t = 1, \dots, q\} \cup \{(j_2'')\}$.

The arguments given in the preceeding paragraphs combine to show that $H_{1,s+1}^{-1}(\text{int}(j_2)) \subseteq N_\delta(H_{1,s+1}^{-1}(\text{int}(j_2'')))$.

$H_{1,s+1}^{-1}(\text{int}(j_2)) \subseteq N_\delta(H_{1,s+1}^{-1}(\text{int}(j_2'')))$. If $u \in \{u_1, \dots, u_k\}$, then

$$H_{1,s+1}^{-1}(\text{int}(j_2)) \cap H_1^{-1}(\text{int}(j_1'')) \subseteq N_{\delta/2}(H_{1,s+1}^{-1}(\text{int}(j_2'')))$$

since

$$H_1^{-1}(\text{int}(j_1'')) \subseteq N_{\delta/2}(H_{1,s+1}^{-1}(\text{int}(j_2''))).$$

If $u \notin \{u_1, \dots, u_k\}$, then $H_{1,s+1}^{-1}(\text{int}(j_2)) \cap H_1^{-1}(\text{int}(j_1''))$ is determined by alterations made with respect to sets of data consisting of integers $1 \leq v_0 \leq v_1 \leq \dots \leq v_t = e$, $\gamma = (j_2'', u'') \in \Gamma_{v_0}$, and chains $(j_2^1, \dots, j_2^t)$ for $l = 1, \dots, t$ satisfying (6.5.1) such that j_2' appears in $(j_2^1, \dots, j_2^t)$, say $j_2' = j_2^q$, and one or both of the following hold: (i) various of the j_2^l 's are subsets of j_1'' ; (ii) $u'' = u$. That part of $H_{1,s+1}^{-1}(\text{int}(j_2)) \cap H_1^{-1}(\text{int}(j_1''))$ resulting from an alteration based on such a set of data will be contained in $N_{\delta/2}(H_{1,s+1}^{-1}(\text{int}(j_2'')))$ since $H_{1,s}^{-1}(\text{int}(j_2))$ will be "pulled inside" by the alteration based on the data consisting of integers $1 \leq v_0 \leq v_1 \leq \dots \leq v_t = e \leq s+1$, $\gamma = (j_2'', u'') \in \Gamma_{v_0}$, and chains $\{(j_2^1, \dots, j_2^t) | t = 1, \dots, t-1\} \cup \{(j_2^1, \dots, j_2^q)\} \cup \{(j_2'')\}$. Consideration of Case 1.e is now completed.

Checking Case 2. $j_2, j_2' \in J_2^{s+1}$ with $j_2 \cap j_2' \neq \emptyset$.

Since the roles of j_2 and j_2' are interchangeable, it suffices to show that $H_{1,s+1}^{-1}(\text{int}(j_2)) \subseteq N_\delta(H_{1,s+1}^{-1}(\text{int}(j_2'')))$. First, observe that (6.3.1)_{s+1} implies that there is a unique $y = (u_1, \dots, u_k) \in \mathfrak{N}_{s+1}$ with $j_2, j_2' \in J_2^y$. For $i = 1, \dots, k$, we have that

$$H_{1,s+1}^{-1}(\text{int}(j_2)) \cap H_1^{-1}(\text{int}(j_1'')) \subseteq H_1^{-1}(\text{int}(j_1'')) \subseteq N_{\delta/2}(H_{1,s+1}^{-1}(\text{int}(j_2''))).$$

For $u \notin \{u_1, \dots, u_k\}$ with $H_{1,s+1}^{-1}(\text{int}(j_2)) \cap H_1^{-1}(\text{int}(j_1'')) \neq \emptyset$, we must show that the intersection is contained in $N_{\delta/2}(H_{1,s+1}^{-1}(\text{int}(j_2'')))$. This intersection is determined by alterations made with respect to sets of data consisting of integers $1 \leq v_0 \leq v_1 \leq \dots \leq v_t = s+1$, $\gamma = (j_2'', u'') \in \Gamma_{v_0}$, and chains $(j_2^1, \dots, j_2^t)$ for $l = 2, \dots, t$ satisfying (6.5.1) such that $j_2 = j_2^t$ and one or both of the following hold: (i) various of the j_2^l 's are subsets of j_1'' ; (ii) $u'' = u$. (Recall that $r_t \leq \mathfrak{S}_s$.) If $r_t = \mathfrak{S}_s$, then the alteration based on the above data will *not* result in $H_{1,s+1}^{-1}(\text{int}(j_2))$ meeting $H_1^{-1}(\text{int}(j_1''))$; the reader

can check this statement by using the definition of $\mathcal{G}_s$ and an argument similar to that used in considering Case 2 for $s = 2$. If $r < \mathcal{G}_s$, then either $j'_2 = j_2^{i_t}$ for some $1 \leq i_t \leq r_t - 1$ or, if such is not the case, then $H_{1,s}^{-1}(\text{int}(j'_2))$ will be altered with respect to the data consisting of the integers $1 \leq v_0 \leq v_1 \leq \dots \leq v_t = s + 1$, $\gamma = (j_2'', u'') \in \Gamma_{v_0}$, and chains $\{(j_2^{1'}, \dots, j_2^{t'}) | t = 1, \dots, t - 1\} \cup \{(j_2^{1'}, \dots, j_2^{t'} = j_2, j_2'')\}$. We leave to the reader to check that in either case the desired containment holds.

(6.7) Letting $H_2 = H_{1,I(\mathcal{Q})}$, the only condition which remains to be verified is (6.1.3)². The reader should first study the effect of the alterations described in (6.5) in order to verify that if $j_2 \in J_2$ and $H_2^{-1}(\text{int}(j_2)) \cap H_1^{-1}(\text{int}(j_1)) \neq \emptyset$ for some $j_1 \in J_1$, then $j_2 \in \text{st}^{\mathcal{G}_{I(\mathcal{Q})-1}}(j_1, J_2)$. Conditions (6.3.2)_s, $s = 2, \dots, I(\mathcal{Q})$, imply that $\text{st}^{\mathcal{G}_{I(\mathcal{Q})}}(j_1, J_2)^* \subseteq \text{int}(\text{st}(j_1, \mathcal{G}_{a_2})^*)$; the latter containment and condition (6.2.1) imply (6.1.3)² as follows. Let $g \in \mathcal{G}_{a_2}$ be such that $j_2 \subseteq g$; hence, $\text{st}(j_2, J_2)^* \subseteq \text{st}^2(g, \mathcal{G}_{a_2})^*$. If $j_1 \in J_1$ is such that $H_2^{-1}(\text{int}(j'_2)) \cap H_1^{-1}(\text{int}(j_1)) \neq \emptyset$ for some $j'_2 \in \text{st}(j_2, J_2)$, then j_1 meets $\text{st}^2(g, \mathcal{G}_{a_2})^*$ since $j'_2 \in \text{st}^{\mathcal{G}_{I(\mathcal{Q})}}(j_1, J_2)^* \subseteq \text{int}(\text{st}(j_1, \mathcal{G}_{a_2})^*)$. Condition (6.1.3)² now follows from (6.2.1). This completes the construction of the $n = 2$ stage.

(6.8) The construction of the $n + 1$ st stage from the n th stage is done exactly as the construction of the 2nd stage from the 1st stage was done *provided* the following change of parameters is made in (6.2). Let $\delta = 1/2^{n+1}$ and let a_{n+1} be such that $\mathcal{G}_{a_{n+1}}$ refines each of the $\mathcal{G}_i$'s used during the construction of the 1st through n th stages. In place of $\xi_2/2^2$ use $\xi_{n+1}/2^{n+1}$, in place of J_1 use J_n , and in place of H_1 use H_n . This completes the proof of Proposition (6.1).

PROOF OF THE MAIN THEOREM.

(6.9) Recall that in §1 we reduced the Main Theorem to the case with f monotone. Using Proposition (6.1) construct triples $R_n: J_n \rightarrow P_n$ by letting $P_n = \{\text{cl}(H_n^{-1}(\text{int}(j_n))) | j_n \in J_n\}$ and letting $R_n(j_n) = \text{cl}(H_n^{-1}(\text{int}(j_n)))$. It is easily verified that the sequence of triples satisfies the hypothesis of Proposition (5.2). Let g be the open mapping obtained from Proposition (5.1) and, as in (4.3), it follows that $g = \lim_{n \rightarrow \infty} H_n$. (We leave to the reader to extract the isotopy $\{h_t\}_{t \in [0, \infty)}$ from the proof of Proposition (6.1).) Finally, to be sure that each $g^{-1}(y)$ is nondegenerate modify the proof of Proposition (6.1) exactly as the proof of Proposition (4.2) was modified in (4.3).
