# TWISTED LUBIN-TATE FORMAL GROUP LAWS, RAMIFIED WITT VECTORS AND (RAMIFIED) ARTIN-HASSE EXPONENTIALS

BY

### MICHIEL HAZEWINKEL

ABSTRACT. For any ring R let  $\Lambda(R)$  denote the multiplicative group of power series of the form  $1+a_1t+\cdots$  with coefficients in R. The Artin-Hasse exponential mappings are homomorphisms  $W_{p,\infty}(k)\to \Lambda(W_{p,\infty}(k))$ , which satisfy certain additional properties. Somewhat reformulated, the Artin-Hasse exponentials turn out to be special cases of a functorial ring homomorphism  $E\colon W_{p,\infty}(-)\to W_{p,\infty}(W_{p,\infty}(-))$ , where  $W_{p,\infty}$  is the functor of infinite-length Witt vectors associated to the prime p. In this paper we present ramified versions of both  $W_{p,\infty}(-)$  and E, with  $W_{p,\infty}(-)$  replaced by a functor  $W_{q,\infty}^F(-)$ , which is essentially the functor of q-typical curves in a (twisted) Lubin-Tate formal group law over A, where A is a discrete valuation ring that admits a Frobenius-like endomorphism  $\sigma$  (we require  $\sigma(a) \equiv a^q \mod m$  for all  $a \in A$ , where m is the maximal idea of A). These ramified-Witt-vector functors  $W_{q,\infty}^F(-)$  do indeed have the property that, if k = A/m is perfect, A is complete, and l/k is a finite extension of k, then  $W_{q,\infty}^F(l)$  is the ring of integers of the unique unramified extension L/K covering l/k.

1. Introduction. For each ring R (commutative with unit element 1) let  $\Lambda(R)$  be the abelian group of power series of the form  $1 + r_1t + r_2t^2 + \cdots$ . Let  $W_{p,\infty}(R)$  be the ring of Witt vectors of infinite length associated to the prime p with coefficients in R. Then the "classical" Artin-Hasse exponential mapping is a map  $E: W_{p,\infty}(k) \to \Lambda(W_{p,\infty}(k))$  defined for all perfect fields k as follows (cf. e.g. [1] and [13]). Let  $\Phi(y)$  be the power series

$$\Phi(y) = \prod_{(p,n)=1} (1 - y^n)^{\mu(n)/n},$$

where  $\mu(n)$  is the Möbius function. Then  $\Phi(y)$  has its coefficients in  $\mathbb{Z}_p$ , cf. e.g. [13]. Because k is perfect every element of  $W_{p,\infty}(k)$  can be written in the form  $\mathbf{b} = \sum_{i=1}^{\infty} \tau(c_i) p^i$ , with  $c_i \in k$ , and  $\tau: k \to W_{p,\infty}(k)$  the unique system of multiplicative representatives. One now defines

$$E \colon W_{p,\infty}(k) \to \Lambda(W_{p,\infty}(k)), \qquad E(\mathbf{b}) = \prod_{i=0}^{\infty} \Phi(\tau(c_i)t)^{p'}.$$

Now let W(-) be the ring functor of big Witt vectors. Then W(-) and  $\Lambda(-)$  are isomorphic, the isomorphism being given by  $(a_1, a_2, \ldots) \mapsto \prod_{i=1}^{\infty} (1 - a_i t^i)$ , cf. [2]. Now there is a canonical quotient map  $W(-) \to W_{p,\infty}(-)$  and composing E with  $\Lambda(-) \simeq W(-)$  and  $W(-) \to W_{p,\infty}(-)$  we find an Artin-Hasse exponential E:  $W_{p,\infty}(k) \to W_{p,\infty}(W_{p,\infty}(k))$ .

1.1. THEOREM. There exists a unique functorial homomorphism of ring-valued functors  $E\colon W_{p,\infty}(-)\to W_{p,\infty}(W_{p,\infty}(-))$  such that for all  $n=0,1,2,\ldots,w_{p,n}\circ E=\mathbf{f}^n$ , where  $\mathbf{f}$  is the Frobenius endomorphism of  $W_{p,\infty}(-)$  and where  $w_{p,n}\colon W_{p,\infty}(W_{p,\infty}(-))\to W_{p,\infty}(-)$  is the ring homomorphism which assigns to the sequence  $(\mathbf{b}_0,\mathbf{b}_1,\ldots)$  of Witt vectors the Witt vector  $\mathbf{b}_0^{p^n}+p\mathbf{b}_1^{p^{n-1}}+\cdots+p^{n-1}\mathbf{b}_{n-1}^p+p^n\mathbf{b}_n$ .

It should be noted that the classical definition of E given above works only for perfect fields of characteristic p > 0. In this form Theorem 1.1 is probably due to Cartier, cf. [5].

Now let A be a complete discrete valuation ring with residue field of characteristic p, such that there exist a power q of p and an automorphism  $\sigma$  of K, the quotient field of A, such that  $\sigma(a) \equiv a^q \mod \mathfrak{m}$  for all  $a \in A$ , where  $\mathfrak{m}$  is the maximal ideal of A. It is the purpose of the present paper to define ramified Witt vector functors  $W_{q,\infty}^F(-)$ :  $\mathbf{Alg}_A \to \mathbf{Alg}_A$ , where  $\mathbf{Alg}_A$  is the category of A-algebras, and a ramified Artin-Hasse exponential mapping  $E: W_{q,\infty}^F(-) \to W_{q,\infty}^F(W_{q,\infty}^F(-))$ .

Artin-Hasse exponential mapping  $E: W_{q,\infty}^F(-) \to W_{q,\infty}^F(W_{q,\infty}^F(-))$ . There is such a ramified-Witt-vector functor  $W_{q,\infty}^F$  associated to every twisted Lubin-Tate formal group law F(X, Y) over A. This last notion is defined as follows. Let  $f(X) = X + a_2 X^2 + \cdots \in K[[X]]$  and suppose that  $a_i \in A$  if q does not divide i and  $a_{qi} - \omega^{-1}\sigma(a_i) \in A$  for all i for a certain fixed uniformizing element  $\omega$ . Then  $F(X, Y) = f^{-1}(f(X) + f(Y)) \in A[[X, Y]]$ , and the formal group laws thus obtained are what we call twisted Lubin-Tate group laws. The Witt-vector functors  $W_{q,\infty}^F(-)$  for varying F are isomorphic if the formal group laws are strictly isomorphic. Now every twisted Lubin-Tate formal group law is strictly isomorphic to one of the form  $G_{\omega}(X, Y) = g_{\omega}^{-1}(g_{\omega}(X) + g_{\omega}(Y))$  with  $g_{\omega}(X) = X + \omega^{-1}X^q + \omega^{-1}\sigma(\omega)^{-1}X^q^2 + \omega^{-1}\sigma(\omega)^{-1}\sigma^2(\omega)^{-1}X^q^3 + \cdots$  which permits us to concentrate on the case  $F(X, Y) = G_{\omega}(X, Y)$  for some  $\omega$ . The formulas are more pleasing in this case, especially because the only constants which then appear are the  $\sigma^i(\omega)$ , which is esthetically attractive, because  $\omega$  is an invariant of the strict isomorphism class of F(X, Y).

The functors  $W_{q,\infty}^F$  and the functor morphisms E are Witt-vector-like and Artin-Hasse-exponential-like in that

- (i)  $W_{q,\infty}^F(B) = \{(b_0, b_1, \dots) | b_i \in B\}$  as a set-valued functor and the A-algebra structure can be defined via suitable Witt-like polynomials  $w_{q,n}^F(Z_0, \dots, Z_n)$ ; cf. below for more details.
- (ii) There exist a  $\sigma$ -semilinear A-algebra homomorphism  $\mathbf{f}$  (Frobenius) and a  $\sigma^{-1}$ -semilinear A-module homomorphism  $\mathbf{V}$  (Verschiebung) with the expected properties, e.g.  $\mathbf{f}\mathbf{V} = \omega$  where  $\omega$  is the uniformizing element of A associated to F, and  $\mathbf{f}(\mathbf{b}) \equiv \mathbf{b}^q \mod \omega W_{a,\infty}^F(B)$ .
- (iii) If k, the residue field of A, is perfect and l/k is a finite field extension, then  $W_{q,\infty}^F(l) = B$ , the ring of integers of the unique unramified extension L/K which covers l/k.
- (iv) The Artin-Hasse exponential E is characterized by  $w_{q,n}^F \circ E = \mathbf{f}^n$  for all  $n = 0, 1, 2, \ldots$

I hope that these constructions will also be useful in a class-field theory setting.

Meanwhile they have been important in formal A-module theory. The results in question have been announced in two notes, [9] and [10], and I now propose to take half a page or so to try to explain these results to some extent.

Let R be a  $\mathbf{Z}_{(p)}$ -algebra and let  $\mathrm{Cart}_p(R)$  be the Cartier-Dieudonné ring. This is a ring "generated" by two symbols  $\mathbf{f}$ ,  $\mathbf{V}$  over  $W_{p,\infty}(R)$  subject to "the relations suggested by the notation used". For each formal group F(X,Y) over R let  $C_p(F;R)$  be its  $\mathrm{Cart}_p(R)$  module of p-typical curves. Finally let  $\hat{W}_{p,\infty}(-)$  be the formal completion of the functor  $W_{p,\infty}(-)$ . Then one has

- (a) the functor  $F \mapsto C_p(F; R)$  is representable by  $\hat{W}_{p,\infty}$  [3].
- (b) The functor  $F \mapsto C_p(F; R)$  is an equivalence of categories between the category of formal groups over R and a certain (explicitly describable) subcategory of  $Cart_n(R)$  modules [3].
- (c) There exists a theory of "lifting" formal groups, in which the Artin-Hasse exponential  $E: W_{p,\infty}(-) \to W_{p,\infty}(W_{p,\infty}(-))$  plays an important rôle. These results relate to the so-called "Tapis de Cartier" and relate to certain conjectures of Grothendieck concerning crystalline cohomology ([4] and [5]).

Now let A be a complete discrete valuation ring with residue field k with q elements (for simplicity and/or nontriviality of the theory). A formal A-module over  $B \in \operatorname{Alg}_A$  is a formal group law F(X, Y) over B together with a ring homomorphism  $\rho_F \colon A \to \operatorname{End}_B(F(X, Y))$ , such that  $\rho_F(a) \equiv aX \mod(\deg 2)$ . Then there exist complete analogues of (a), (b), (c) above for the category of formal A-modules over B. Here the rôle of  $C_p(F; R)$  is taken over by the q-typical curves  $C_q(F; B)$ ,  $W_{p,\infty}(-)$  and  $\hat{W}_{p,\infty}$  are replaced by ramified-Witt-vector functors  $W_{q,\infty}^{\pi}(-)$  and  $\hat{W}_{q,\infty}^{\pi}(-)$  associated to an untwisted, i.e.  $\sigma = \operatorname{id}$ , Lubin-Tate formal group law over A with associated uniformizing element  $\pi$ . Finally, the rôle of E in (c) is taken over by the ramified Hasse-Witt exponential  $W_{q,\infty}^{\pi}(-) \to W_{q,\infty}^{\pi}(W_{q,\infty}^{\pi}(-))$ .

As we remarked in (i) above, it is perfectly possible to define and analyse  $W_{q,\infty}^F(-)$  by starting with the polynomials  $w_{q,n}^F(Z)$  and then proceeding along the lines of Witt's original paper. And, in fact, in the untwisted case, where k is a field of q-elements, this has been done, independently of this paper, and independently of each other by E. Ditters [7], V. Drinfel'd [8], J. Casey (unpublished) and, very possibly, several others. In this case the relevant polynomials are of course the polynomials  $X_0^{q^n} + \pi X_1^{q^{n-1}} + \cdots + \pi^{n-1} X_{n-1}^q + \pi^n X_n$ .

Of course the twisted version is necessary if one wants to describe also all ramified discrete valuation rings with not necessarily finite residue fields. A second main reason for considering "twisted formal A-modules" is that there exist no nontrivial formal A-modules if the residue field of A is infinite.

Let me add that, in my opinion, the formal group law approach to (ramified) Witt-vectors is technically and conceptually easier. Witness, e.g. the proof of Theorem 6.6 and the ease with which one defines Artin-Hasse exponentials in this setting (cf. §§6.1 and 6.5 below). Also this approach removes some of the mystery and exclusive status of the particular Witt polynomials  $X_0^{p^n} + pX_1^{p^{n-1}} + \cdots + p^nX_n$  (unramified case),  $X_0^{q^n} + \pi X_1^{q^{n-1}} + \cdots + \pi^nX_n$  (untwisted ramified case),

 $X_0^{q^n}+\sigma^{n-1}(\omega)X_1^{q^{n-1}}+\sigma^{n-1}(\omega)\sigma^{n-2}(\omega)X_2^{q^{n-2}}+\cdots+\sigma^{n-1}(\omega)\cdots\sigma(\omega)\omega X_n$  (twisted ramified case). From the theoretical (if not the esthetic and/or computational) point of view all polynomials  $\tilde{w}_{q,n}(X_0,\ldots,X_n)=a_n^{-1}(a_nX_0^{q^n}+a_{n-1}X_1^{q^{n-1}}+\cdots+a_0X_n)\in A[X]$  are equally good, provided  $a_0=1,a_2,a_3,\ldots$  is a sequence of elements of K such that  $a_i-\omega^{-1}\sigma(a_{i-1})\in A$  for all  $i=1,2,\ldots$  (cf. in

## 2. The functional-equation-integrality lemma.

this connection also [6]).

2.1. The setting. Let A be a discrete valuation ring with maximal ideal m, residue field k of characteristic p>0 and field of quotients K. Both characteristic zero and characteristic p>0 are allowed for K. We use v to denote the normalized exponential valuation on K and  $\omega$  always denotes a uniformizing element, i.e.  $v(\omega)=1$  and  $m=\omega A$ . We assume that there exist a power q of p and an automorphism  $\sigma$  of K such that

$$\sigma(\mathfrak{m}) = \mathfrak{m}, \quad \sigma a \equiv a^q \mod \mathfrak{m} \quad \text{for all } a \in A.$$
 (2.2)

The ring A does not need to be complete.

Further let  $B \in \mathbf{Alg}_A$ , the category of A-algebras. We suppose that B is A-torsion free (i.e. that the natural map  $B \to B \otimes_A K$  is injective) and we suppose that there exists an endomorphism  $\tau \colon B \otimes_A K \to B \otimes_A K$  such that

$$\tau(b) \equiv b^q \bmod mB \quad \text{for all } b \in B. \tag{2.3}$$

Finally let f(X) be any power series over  $B \otimes_{A} K$  of the form

$$f(X) = b_1 X + b_2 X^2 + \cdots, \quad b_i \in B, b_1 \text{ a unit of } B,$$
 (2.4)

for which there exists a uniformizing element  $\omega \in A$  such that

$$f(X) - \omega^{-1} \tau_{\bullet} f(X^q) \in B[[X]]$$
 (2.5)

where  $\tau_*$  means "apply  $\tau$  to the coefficients". In terms of the coefficients  $b_i$  of f(X) condition (2.5) means that

$$b_i \in B$$
 if q does not divide i,

$$b_{ai} - \omega^{-1} \tau(b_i) \in B$$
 for all  $i = 1, 2, ...$  (2.6)

- 2.7. FUNCTIONAL EQUATION LEMMA. Let A, B,  $\sigma$ ,  $\tau$ , K, p, q, f(X),  $\omega$  be as in 2.1 above such that (2.2.)–(2.6) hold. Then we have
- (i)  $F(X, Y) = f^{-1}(f(X) + f(Y))$  has its coefficients in B and hence is a commutative one-dimensional formal group law over B. (Here  $f^{-1}(X)$  is the "inverse function" power series of f(X); i.e.  $f^{-1}(f(X)) = X$ .)
- (ii) If  $g(X) \in B[[X]]$ , g(0) = 0 and h(X) = f(g(X)) then we have  $h(X) \omega^{-1}\tau_*h(X^q) \in B[[X]]$ .
- (iii) If  $h(X) \in B \otimes_A K[[X]]$ , h(0) = 0 and  $h(X) \omega^{-1} \tau_* h(X^q) \in B[[X]]$ , then  $f^{-1}(h(X)) \in B[[X]]$ .
- (iv) If  $\alpha(X) \in B[[X]]$ ,  $\beta(X) \in B \otimes_A K[[X]]$ ,  $\alpha(0) = \beta(0) = 0$  and  $r, m \in \mathbb{N} = \{1, 2, \ldots\}$ , then  $\alpha(X) \equiv \beta(X) \mod(\omega'B)$ , degree  $m \in f(\alpha(X)) \equiv f(\beta(X)) \mod(\omega'B)$ , degree  $m \in f(\alpha(X))$ .

PROOF. This lemma is a quite special case of the functional equation lemmas of [11, cf. §§2.2 and 10.2]. There are also infinite-dimensional versions. Here is a quick proof. First notice that (2.6) implies (with induction) that

$$b_i \in \omega^{-i} B$$
 if j is not divisible by  $q^{i+1}$ . (2.8)

We now first prove a more general form of (ii). Let  $g(Z) = g(Z_1, \ldots, Z_m) \in B[[Z_1, \ldots, Z_m]], g(0) = 0$ . Then by the hypotheses of 2.1 we have

$$g(Z_1,\ldots,Z_m)^{q'n} \equiv \tau_{\star} g(Z_1^q,\ldots,Z_m^q)^{q'^{-1}n} \operatorname{mod}(\omega'B). \tag{2.9}$$

Combining (2.8) and (2.9) and using (2.6) we see that mod(B[[X]]) we have

$$h(Z) = f(g(Z)) = \sum_{i=1}^{\infty} b_i g(Z)^i \equiv \sum_{j=1}^{\infty} b_{qj} g(Z)^{qj} \equiv \omega^{-1} \sum_{j=1}^{\infty} \tau(b_j) g(Z)^{qj}$$
  
$$\equiv \omega^{-1} \sum_{j=1}^{\infty} \tau(b_j) \tau_* g(Z^q)^j = \omega^{-1} \tau_* f(\tau_* g(Z^q)) = \omega^{-1} \tau_* h(Z^q).$$

This proves (ii). To prove (i) we write  $F(X, Y) = F_1(X, Y) + F_2(X, Y) + \cdots$ , where  $F_n(X, Y)$  is homogeneous of degree n. We now prove by induction that  $F_n(X, Y) \in B[X, Y]$  for all  $n = 1, 2, \ldots$ . The induction starts because  $F_1(X, Y) = X + Y$ . Now assume that  $F_1(X, Y), \ldots, F_m(X, Y) \in B[X, Y]$ . We know that  $f(F(X, Y)) \equiv b_1 F_{m+1}(X, Y) + f(g(X, Y))$  mod(degree m + 2), where  $g(X, Y) = F_1(X, Y) + \cdots + F_m(X, Y)$ . Hence, using the more general form of (ii) proved just above, we find mod(B[X, Y], degree m + 2):

$$f(F(X, Y)) \equiv b_1 F_{m+1}(X, Y) + f(g(X, Y))$$

$$\equiv b_1 F_{m+1}(X, Y) + \omega^{-1} \tau_* f(\tau_* g(X^q, Y^q))$$

$$\equiv b_1 F_{m+1}(X, Y) + \omega^{-1} \tau_* f(\tau_* F(X^q, Y^q))$$

$$= b_1 F_{m+1}(X, Y) + \omega^{-1} \tau_* f(X^q) + \omega^{-1} \tau_* f(Y^q)$$

$$\equiv b_1 F_{m+1}(X, Y) + f(X) + f(Y) = b_1 F_{m+1}(X, Y) + f(F(X, Y))$$

where we have used the defining relation f(F(X, Y)) = f(X) + f(Y), which implies  $\tau_* f(\tau_* F(X^q, Y^q)) = \tau_* f(X^q) + \tau_* f(Y^q)$ , and where we have also used the fact that  $F(X, Y) \equiv g(X, Y) \mod(\deg m + 1) \Rightarrow F(X^q, Y^q) \equiv g(X^q, Y^q) \mod(\deg m + 2)$ . It follows that  $b_1 F_{m+1}(X, Y) \equiv 0 \mod(B[[X, Y]], \deg m + 2)$  and hence  $F_{m+1}(X, Y) \in B[X, Y]$  because  $b_1$  is a unit.

The proof of (iii) is completely analogous to the proof of (i).

The implication  $\Rightarrow$  of (iv) is easy to prove. If  $\alpha(X) \equiv \beta(X) \mod(\omega'B)$ , degree m) and  $\alpha(X) \in B[[X]]$  then  $\alpha(X)^{q^{ij}} \equiv \beta(X)^{q^{ij}} \mod(\omega'^{i}B)$ , degree m) which, combined with (2.8), proves that  $f(\alpha(X)) \equiv f(\beta(X)) \mod(\omega'B)$ , degree m). To prove the inverse implication  $\Leftarrow$  of (iv) we first do the special case

$$f(\beta(X)) \equiv 0 \mod(\omega' B, \text{ degree } m) \Rightarrow \beta(X) \equiv 0 \mod(\omega' B, \text{ degree } m).$$

Now  $\beta(X) \equiv 0 \mod(\text{degree 1})$ , hence  $f(\beta(X)) = b_1 \beta(X) + b_2 \beta(X)^2 + \cdots \equiv 0 \mod(\omega'B, \text{ degree } m)$ , implies  $\beta(X) \equiv 0 \mod(\omega'B, \text{ degree 2})$ , if m > 2 (if m = 1 there is nothing to prove), because  $b_1$  is a unit. Now assume with induction that

 $\beta(X) \equiv 0 \mod(\omega'B, \text{ degree } n)$  for some n < m. Then, because  $\beta(X) \equiv 0 \mod(\text{degree} 1)$  we have  $\beta(X)^i \equiv 0 \mod(\omega^n B, \text{ degree}(n+i-1))$  and hence  $b_j\beta(X)^j \equiv 0 \mod(\omega'B, \text{ degree } n+1)$  if j > 2. Hence  $f(\beta(X)) \equiv 0 \mod(\omega'B, \text{ degree } m)$  then gives  $b_1\beta(X) \equiv 0 \mod(\omega'B, \text{ degree } n+1)$ , so that  $\beta(X) \equiv 0 \mod(\omega'B, \text{ degree } n+1)$  because  $b_1$  is a unit. This proves this special case of (iv). Now let  $f(\alpha(X)) \equiv f(\beta(X)) \mod(\omega'B, \text{ degree } m)$ . Write  $\gamma(X) = f(\beta(X)) - f(\alpha(X))$  and  $\delta(X) = f^{-1}(\gamma(X))$ . Then  $\delta(X) \equiv 0 \mod(\omega'B, \text{ degree } m)$  by the special case just proved, and  $\beta(X) = f^{-1}(f(\alpha(X)) + f(\delta(X))) = F(\alpha(X), \delta(X)) \equiv \alpha(X) \mod(\omega'B, \text{ degree } m)$  because F(X, Y) has integral coefficients, F(X, 0) = 0 and because  $\alpha(X)$  is integral. This concludes the proof of the Functional Equation Lemma 2.7.

### 3. Twisted Lubin-Tate formal A-modules.

3.1. Construction and definition. Let  $A, K, k, p, m, \sigma, q$  be as in 2.1 above. We consider a power series  $f(X) = X + c_2X^2 + \cdots \in K[[X]]$  such that there exists a uniformizing element  $\omega \in m$  such that

$$f(X) - \omega^{-1} \sigma_{\bullet} f(X^q) \in A[[X]]. \tag{3.2}$$

There are many such power series. The simplest are obtained as follows. Choose a uniformizing element  $\omega$  of A. Define

$$g_{\omega}(X) = X + \omega^{-1}X^{q} + \omega^{-1}\sigma(\omega)^{-1}X^{q^{2}} + \omega^{-1}\sigma(\omega)^{-1}\sigma^{2}(\omega)^{-1}X^{q^{3}} + \cdots$$
 (3.3)

Given such a power series f(X), part (i) of the Functional Equation Lemma says that

$$F(X, Y) = f^{-1}(f(X) + f(Y))$$
(3.4)

has its coefficients in A, and hence is a one-dimensional formal group law over A. We shall call the formal group laws thus obtained twisted Lubin-Tate formal A-modules over A. The twisted Lubin-Tate formal A-module is called q-typical if the power series f(X) that it is obtained from is of the form

$$f(X) = X + a_1 X^q + a_2 X^{q^2} + \cdots$$
 (3.5)

From now on all twisted Lubin-Tate formal A-modules will be assumed to be q-typical. This is hardly a restriction because of Lemma 3.6 below.

3.6. LEMMA. Let  $f(X) = X + c_2 X^2 + \cdots \in K[[X]]$  be such that (3.2) holds. Let  $\hat{f}(X) = \sum_{i=0}^{\infty} a_i X^{q^i}$  with  $a_0 = 1$ ,  $a_i = c_{q^i}$ . Then  $u(X) = \hat{f}^{-1}(f(X)) \in A[[X]]$  so that F(X, Y) and  $\hat{F}(X, Y)$  are strictly isomorphic formal group laws over A.

PROOF. It follows from the definition of  $\hat{f}(X)$ , that  $\hat{f}(X)$  also satisfies (3.2). The integrality of u(X) now follows from part (iii) of the Functional Equation Lemma.

3.7. Remarks. Let k, the residue field of K, be finite with q elements, and let  $\sigma = id$ . Then the twisted Lubin-Tate formal A-modules over A as defined above are precisely the Lubin-Tate formal group laws defined in [12], i.e. they are precisely the formal A-modules of A-height 1. If k is infinite there exist no nontrivial formal A-modules (cf. [11, Corollary 21.4.23]). This is a main reason for also considering twisted Lubin-Tate formal group laws.

- 3.8. Remark. Let  $f(X) \in K[[X]]$  be such that (3.2) holds for a certain uniformizing element  $\omega$ . Then  $\omega$  is uniquely determined by f(X), because  $a_i \omega^{-1}\sigma(a_{i-1}) \in A \Rightarrow \omega \equiv a_i^{-1}\sigma(a_{i-1}) \mod \omega^{2i}A$  as  $v(a_i) = -i$ . Using parts (ii) and (iii) of the Functional Equation Lemma we see that  $\omega$  is in fact an invariant of the strict isomorphism class of F(X, Y). Inversely, given  $\omega$  we can construct  $g_{\omega}(X)$  as in (3.3) and then  $g_{\omega}^{-1}(f(X)) = u(X)$  is integral so that F(X, Y) and  $G_{\omega}(X, Y) = g_{\omega}^{-1}(g_{\omega}(X) + g_{\omega}(Y))$  are strictly isomorphic formal group laws. In case #k = q and  $\sigma = \mathrm{id}$ ,  $\omega$  is in fact an invariant of the isomorphism class of F(X, Y). For some more results on isomorphisms and endomorphisms of twisted Lubin-Tate formal A-modules cf. [11], especially §§8.3, 20.1, 21.8, 24.5.
- **4. Curves and q-typical curves.** Let F(X, Y) be a q-typical twisted Lubin-Tate formal A-module obtained via (3.4) from a power series  $f(X) = X + a_1 X^q + a_2 X^{q^2} + \cdots$ .
- 4.1. Curves. Let  $\operatorname{Alg}_A$  be the category of A-algebras. Let  $B \in \operatorname{Alg}_A$ . A curve in F over B is simply a power series  $\gamma(t) \in B[[t]]$  such that  $\gamma(0) = 0$ . Two curves can be added by the formula  $\gamma_1(t) +_F \gamma_2(t) = F(\gamma_1(t), \gamma_2(t))$ , giving us an abelian group C(F; B). Further, if  $\phi: B_1 \to B_2$  is in  $\operatorname{Alg}_A$ , then  $\gamma(t) \mapsto \phi_* \gamma(t)$  (="apply  $\phi$  to the coefficients") defines a homomorphism of abelian groups  $C(F; B_1) \to C(F; B_2)$ . This defines an abelian-group-valued functor C(F; -):  $\operatorname{Alg}_A \to \operatorname{Ab}$ . There is a natural filtration on C(F; -) defined by the filtration subgroups  $C^n(F; B) = \{\gamma(t) \in C(F; B) | \gamma(t) \equiv 0 \mod(\text{degree } n)\}$ . The groups C(F; B) are complete with respect to the topology defined by the filtration  $C^n(F; B), n = 1, 2, \ldots$

The functor C(F; -) is representable by the A-algebra  $A[S] = A[S_1, S_2, ...]$ . The isomorphism  $Alg_A(A[S], B) \xrightarrow{\sim} C(F; B)$  is given by

$$\phi \mapsto \sum_{i=1}^{\infty} {}^{F} \phi(S_i) t^i,$$

i.e. by  $\phi \mapsto \phi_* \gamma_S(t)$ , where  $\gamma_S(t)$  is the "universal curve"

$$\gamma_{S}(t) = \sum_{i=1}^{\infty} {}^{F} S_{i} t^{i} \in C(F; A[S]).$$

Here the superscript F means that we sum in the group C(F; B) just defined (to avoid possible confusion with ordinary sums).

4.2. q-typification. Let  $\gamma_S(t) \in C(F; A[S])$  be the universal curve. Consider the power series

$$h(t) = f(\gamma_S(t)) = \sum_{i=1}^{\infty} x_i(S)t^i.$$

Let  $\tau: K[S] \to K[S]$  be the ring endomorphism defined by  $\tau(a) = \sigma(a)$  for  $a \in K$  and  $\tau(S_i) = S_i^q$  for  $i = 1, 2, \ldots$ . Then the hypotheses of 2.1 are fulfilled and it follows from part (ii) of the Functional Equation Lemma that  $h(t) - \omega^{-1}\tau_*h(t^q) \in A[S][[t]]$ . Now let  $\hat{h}(t) = \sum_{i=0}^{\infty} x_{q'}(S)t^{q'}$ . Then, obviously, also  $\hat{h}(t) - \omega^{-1}\tau_*\hat{h}(t^q) \in A[S][[t]]$  and by part (iii) of the Functional Equation Lemma it follows that

$$\varepsilon_q \gamma_S(t) = f^{-1} \left( \sum_{i=0}^{\infty} x_{q^i}(S) t^{q^i} \right) \tag{4.3}$$

is an element of A[S][[t]]. We now define a functorial group homomorphism  $\varepsilon_q$ :  $C(F; -) \to C(F; -)$  by the formula

$$\varepsilon_{q}\gamma(t) = (\phi_{\gamma})_{*}(\varepsilon_{q}\gamma_{S}(t)) \tag{4.4}$$

for  $\gamma(t) \in C(F; B)$ , where  $\phi_{\gamma} \colon A[S] \to B$  is the unique A-algebra homomorphism such that  $(\phi_{\gamma})_* \gamma_S(t) = \gamma(t)$ .

4.5. LEMMA. Let B be A-torsion free so that  $B \to B \otimes_A K$  is injective. Then we have for all  $\gamma(t) \in C(F; B)$ ,

$$f(\gamma(t)) = \sum_{i=1}^{\infty} b_i t^i \Rightarrow f(\varepsilon_q \gamma(t)) = \sum_{i=0}^{\infty} b_{qi} t^{qi}$$
 (4.6)

and  $\varepsilon_a C(F; B) = \{ \gamma(t) \in C(F; B) | f(\gamma(t)) = \sum_i c_i t^{q^i} \text{ for certain } c_i \in B \otimes_A K \}.$ 

PROOF. Immediate from (4.3) and (4.4).

4.7. Lemma.  $\varepsilon_a$  is a functorial, idempotent, group endomorphism of C(F; -).

PROOF.  $\varepsilon_q$  is functorial by definition. The facts that  $\varepsilon_q \varepsilon_q = \varepsilon_q$  and that  $\varepsilon_q$  is a group homomorphism are obvious from Lemma 4.5 in case B is A-torsion free. Functoriality then implies that these properties hold for all A-algebras B.

4.8. The functor  $C_q(F; -)$  of q-typical curves. We now define the abelian-group-valued functor  $C_q(F; -)$  as

$$C_q(F; -) = \varepsilon_q C(F; -). \tag{4.9}$$

For each  $n \in \mathbb{N} \cup \{0\}$  let  $C_q^{(n)}(F; B)$  be the subgroup  $C_q(F; B) \cap C_q^{(n)}(F; B)$ . These groups define a filtration on  $C_q(F; B)$ , and  $C_q(F; B)$  is complete with respect to the topology defined by this filtration.

The functor  $C_q(F; -)$  is representable by the A-algebra  $A[T] = A[T_0, T_1, \dots]$ . Indeed, writing  $f(X) = \sum_{i=0}^{\infty} a_i X^{q^i}$  we have

$$f(\gamma_S(t)) = f\left(\sum_{i=1}^{\infty} {}^F S_i t^i\right) = \sum_{j=0}^{\infty} \sum_{i=1}^{\infty} a_j S_i^{q'} t^{q'i}$$

and it follows that

$$\varepsilon_q \gamma_S(t) = \sum_{i=0}^{\infty} {}^F S_{qi} t^{qi}.$$

From this one easily obtains that the functor  $C_q(F; -)$  is representable by A[T]. The isomorphism  $\operatorname{Alg}_A(A[T], B) \xrightarrow{\sim} C_q(F; B)$  is given by

$$\phi \mapsto \sum_{i=0}^{\infty} {}^{F} \phi(T_i) t^{q^i} = \phi_{*}(\gamma_T(t)),$$

where  $\gamma_T(t)$  is the universal q-typical curve

$$\gamma_T(t) = \sum_{i=0}^{\infty} {}^F T_i t^{q^i} \in C_q(F; A[T]). \tag{4.10}$$

4.11. REMARKS. The explicit formulas of 4.8 above depend on the fact that F was supposed to be q-typical. In general slightly more complicated formulae hold. For arbitrary formal groups q-typification (i.e.  $\epsilon_q$ ) is not defined (unless q = p). But a similar notion of q-typification exists for formal A-modules of any height and any dimension if # k = q.

## 5. The A-algebra structure on $C_a(F; -)$ , Frobenius and Verschiebung.

5.1. From now on we assume that  $f(X) = g_{\omega}(X) = X + \omega^{-1}X^q + \omega^{-1}\sigma(\omega)^{-1}X^{q^2} + \cdots$  for a certain uniformizing element  $\omega$ . Otherwise we keep the notations and assumptions of §4. Thus we now have  $a_i^{-1} = \omega\sigma(\omega) \dots \sigma^{i-1}(\omega)$ ,  $a_0 = 1$ . This restriction to "logarithms" f(X) of the form  $g_{\omega}(X)$  is not very serious, because every twisted Lubin-Tate formal A-module over A is strictly isomorphic to a  $G_{\omega}(X, Y)$ , (cf. Remark 3.8), and one can use the strict isomorphism  $g_{\omega}^{-1}(f(X))$  to transport all the extra structure on  $C_q(F; -)$  which we shall define in this section. The restriction  $f(X) = g_{\omega}(X)$  does have the advantage of simplifying the defining formulas (5.4), (5.5), (5.8), ... somewhat, and it makes them look rather more natural especially in view of the fact that  $\omega$ , the only "constant" which appears, is an invariant of strict isomorphism classes of twisted Lubin-Tate formal A-modules (cf. Remark 3.8 above).

In this section we shall define an A-algebra structure on the functor  $C_q(F; -)$  and two endomorphisms  $\mathbf{f}_{\omega}$  and  $\mathbf{V}_q$ . These constructions all follow the same pattern, the same pattern as was used to define and analyse  $\varepsilon_q$  in §4 above. First one defines the desired operations for universal curves like  $\gamma_T(t)$  which are defined over rings like A[T], which, and this is the crucial point, admit an endomorphism  $\tau \colon K[T] \to K[T]$ , viz.  $\tau(a) = \sigma(a)$ ,  $\tau(T_i) = T_i^q$ , which extends  $\sigma$  and which is such that  $\tau(x) \equiv x^q \mod \omega A[T]$ . In such a setting the Functional Equation Lemma assures us that our constructions do not take us out of C(F; -) or  $C_q(F; -)$ . Second, the definitions are extended via representability and functoriality, and thirdly, one derives a characterization which holds over A-torsion free rings, and using this, one proves the various desired properties like associativity of products,  $\sigma$ -semilinearity of  $\mathbf{f}_{\omega}$ , etc.

5.2. Constructions. Let  $\gamma_T(t)$  be the universal q-typical curve (4.10). We write

$$f(\gamma_T(t)) = \sum_{i=0}^{\infty} x_i(T)t^{q^i}.$$
 (5.3)

Let  $f(X) = g_{\omega}(X) = \sum_{i=0}^{\infty} a_i X^{q^i}$ , i.e.  $a_i = \omega^{-1} \sigma(\omega)^{-1} \dots \sigma^{i-1}(\omega)^{-1}$  and let  $a \in A$ . We define

$$\{a\}_{F}\gamma_{T}(t) = f^{-1}\left(\sum_{i=0}^{\infty} \sigma^{i}(a)x_{i}(T)t^{q^{i}}\right),$$
 (5.4)

$$\mathbf{f}_{\omega}\gamma_{T}(t) = f^{-1} \left( \sum_{i=0}^{\infty} \sigma^{i}(\omega) x_{i+1}(T) t^{q^{i}} \right). \tag{5.5}$$

The Functional Equation Lemma now assures us that (5.4) and (5.5) define elements of C(F; A[T]), which then are in  $C_q(F; A[T])$  by Lemma 4.5. To illustrate

this we check the hypotheses necessary to apply (iii) of 2.7 in the case of  $\mathbf{f}_{\omega}$ . Let  $\tau$ :  $K[T] \to K[T]$  be as in 5.1 above. Then by part (ii) of the Functional Equation Lemma we know that

$$x_0 \in A[T], \quad x_{i+1} - \omega^{-1}\tau(x_i) = c_i \in A[T].$$

It follows by induction that

$$x_i \in \omega^{-i} A[T] \tag{5.6}$$

and we also know that

$$v(a_i^{-1}) = v(\omega \sigma(\omega) \dots \sigma^{i-1}(\omega)) = i$$
 (5.7)

where v is the normalized exponential valuation on K. We thus have  $\sigma^0(\omega)x_1 = \omega x_1 \in A[T]$  and

$$\sigma^{i}(\omega)x_{i+1} - \omega^{-1}\tau(\sigma^{i-1}(\omega)x_{i}) = \sigma^{i}(\omega)c_{i} + \sigma^{i}(\omega)\omega^{-1}\tau(x_{i}) - \omega^{-1}\tau(\sigma^{i-1}(\omega)x_{i})$$
$$= \sigma^{i}(\omega)c_{i} \in A[T].$$

Hence part (iii) of the Functional Equation Lemma says that  $\mathbf{f}_{\omega}\gamma_{T}(t) \in C(F; A[T])$ .

To define the multiplication on  $C_q(F; -)$  we need two independent universal q-typical curves. Let  $\gamma_T(t) = \sum^F T_i t^{q^i}$ ,  $\delta_{\hat{T}}(t) = \sum^F \hat{T}_i t^{q^i} \in C_q(F; A[T; \hat{T}])$ . We define

$$\gamma_T(t) * \delta_{\hat{T}}(t) = f^{-1} \left( \sum_{i=0}^{\infty} a_i^{-1} x_i y_i t^{q'} \right)$$
 (5.8)

where  $f(\gamma_T(t)) = \sum x_i t^{q^i}$ ,  $f(\delta_{\hat{T}}(t)) = \sum y_i t^{q^i}$ . To prove that (5.8) defines something integral we proceed as usual. We have  $x_0, y_0 \in A[T; \hat{T}]$ ,  $x_{i+1} - \omega^{-1}\tau(x_i) = c_i \in A[T; \hat{T}]$ ,  $y_{i+1} - \omega^{-1}\tau(y_i) = d_i \in A[T; \hat{T}]$ , where  $\tau \colon K[T; \hat{T}] \to K[T; \hat{T}]$  is defined by  $\tau(a) = \sigma(a)$  for  $a \in K$ , and  $\tau(T_i) = T_i^q$ ,  $\tau(\hat{T}_i) = T_i^q$ ,  $i = 0, 1, 2, \ldots$  Then  $a_0x_0y_0 = x_0y_0 \in A[T; \hat{T}]$  and

$$a_{i+1}^{-1}x_{i+1}y_{i+1} - \omega^{-1}\tau(a_i^{-1}x_iy_i)$$

$$= \omega\sigma(a_i)^{-1}(c_i + \omega^{-1}\tau(x_i))(d_i + \omega^{-1}\tau(y_i)) - \omega^{-1}\sigma(a_i^{-1})\tau(x_i)\tau(y_i)$$

$$= \omega\sigma(a_i^{-1})c_id_i + \sigma(a_i)^{-1}(c_i\tau(y_i) + d_i\tau(x_i)) \in A[T; \hat{T}]$$

by (5.6) and (5.7).

5.9. DEFINITION. Let  $\gamma(t)$ ,  $\delta(t)$  be two q-typical curves in F over  $B \in \mathbf{Alg}_A$ . Let  $\phi$ :  $A[T] \to B$  be the unique A-algebra homomorphism such that  $\phi_* \gamma_T(t) = \gamma(t)$ , and let  $\psi$ :  $A[T; \hat{T}] \to B$  be the unique A-algebra homomorphism such that  $\psi_* \gamma_T(t) = \gamma(t)$ ,  $\psi_* \delta_{\hat{T}}(t) = \delta(t)$ . Let  $a \in A$ . We define

$$\{a\}_{F}\gamma(t) = \phi_{*}(\{a\}_{F}\gamma_{T}(t)),$$
 (5.10)

$$\mathbf{f}_{\omega}\gamma(t) = \phi_{\star}(\mathbf{f}_{\omega}\gamma_{T}(t)), \tag{5.11}$$

$$\gamma(t) * \delta(t) = \psi_*(\gamma_T(t) * \delta_T(t)). \tag{5.12}$$

5.13. Characterizations. Let B be an A-torsion free A-algebra; i.e.  $B \to B \otimes_A K$  is injective, then the definitions (5.10)–(5.12) are characterized by the implications

$$f(\gamma(t)) = \sum_{i=0}^{\infty} x_i t^{q^i} \Rightarrow f(\{a\}_F \gamma(t)) = \sum_{i=0}^{\infty} \sigma^i(a) x_i t^{q^i},$$
 (5.14)

$$f(\gamma(t)) = \sum_{i=0}^{\infty} x_i t^{q^i} \Rightarrow f(\mathbf{f}_{\omega} \gamma(t)) = \sum_{i=0}^{\infty} \sigma^i(\omega) x_{i+1} t^{q^i}, \tag{5.15}$$

$$f(\gamma(t)) = \sum_{i=0}^{\infty} x_i t^{q^i}, \quad f(\delta(t)) = \sum_{i=0}^{\infty} y_i t^{q^i} \Rightarrow$$

$$f(\gamma(t) * \delta(t)) = \sum_{i=0}^{\infty} a_i^{-1} x_i y_i t^{q^i}.$$
 (5.16)

This follows immediately from (5.4), (5.5) (5.8) compared with (5.10)–(5.12), because  $\phi_*$  and  $\psi_*$  are defined by applying  $\phi$  and  $\psi$  to coefficients, and because  $\gamma(t) \mapsto f(\gamma(t))$  is injective, if B is A-torsion free.

5.17. THEOREM. The operators  $\{a\}_F$  defined by (5.10) define a functorial A-module structure on  $C_q(F; -)$ . The multiplication \* defined by (5.12) then makes  $C_q(F; -)$  an A-algebra-valued functor, with as unit element the q-typical curve  $\gamma_0(t) = t$ . The operator  $\mathbf{f}_{\omega}$  is a  $\sigma$ -semilinear A-algebra homomorphism, i.e.  $\mathbf{f}_{\omega}$  is a unit and multiplication-preserving group endomorphism such that  $\mathbf{f}_{\omega}\{a\}_F = \{\sigma(a)\}_F \mathbf{f}_{\omega}$ .

PROOF. In case B is A-torsion free the various identities in  $C_q(F; B)$  like  $(\{a\}_F \gamma(t)) * \delta(t) = \{a\}_F (\gamma(t) * \delta(t)), \quad \gamma(t) * (\delta(t) +_F \varepsilon(t)) = (\gamma(t) * \delta(t)) +_F (\gamma(t) * \varepsilon(t)), \dots$  are obvious from the characterizations (5.14)–(5.16). The theorem then follows by functoriality.

5.18. Verschiebung. We now define the Verschiebung operator  $V_q$  on  $C_q(F; -)$  by the formula  $V_q \gamma(t) = \gamma(t^q)$ . (It is obvious from Lemma 4.5 that this takes q-typical curves into q-typical curves.) In terms of the logarithm f(X) one has for curves  $\gamma(t)$  over A-torsion free A-algebras B,

$$f(\gamma(t)) = \sum_{i=0}^{\infty} x_i t^{q^i} \Rightarrow f(\mathbf{V}_q \gamma(t)) = \sum_{i=0}^{\infty} x_i t^{q^{i+1}}.$$
 (5.19)

5.20. THEOREM. For q-typical curves  $\gamma(t)$  in F over an A-algebra B,

$$\mathbf{f}_{\omega}\mathbf{V}_{a}\gamma(t) = \{\omega\}_{F}\gamma(t),\tag{5.21}$$

$$\mathbf{f}_{\omega}\gamma(t) \equiv \gamma(t)^{*q} \mod\{\omega\}_F C_q(F; B). \tag{5.22}$$

PROOF. (5.21) is immediate from (5.14), (5.15) and (5.19) in the case of A-torsion free B and then follows in general by functoriality. The proof of (5.22) is a bit longer. It suffices to prove (5.22) for curves  $\gamma(t) \in C_q(F; A[T])$ . In fact it suffices to prove (5.22) for  $\gamma(t) = \gamma_T(t)$ , the universal curve of (4.10). Let

$$\delta(t) = f^{-1} \left( \sum_{i=0}^{\infty} y_i t^{q^i} \right), \qquad y_i = x_{i+1} - \sigma^i(\omega)^{-1} a_i a_i^{-q} x_i^q, \tag{5.23}$$

where the  $x_i$ ,  $i=0,1,2,\ldots$ , are determined by  $f(\gamma(t))=\sum x_i t^{q^i}$ . It then follows from (5.14)–(5.16) that indeed  $\mathbf{f}_{\omega}\gamma(t)-\gamma(t)^{*q}=\{\omega\}_F\delta(t)$ , provided that we can show that  $\delta(t)$  is integral, i.e. that  $\delta(t)\in C_q(F;A[T])$ . To see this it suffices to show

that  $y_0 \in A[T]$  and  $y_{i+1} - \omega^{-1}\tau(y_i) \in A[T]$  because of part (iii) of the Functional Equation Lemma. Let  $c_i = x_{i+1} - \omega^{-1}\tau(x_i) \in A[T]$ . Then

$$y_0 = x_1 - \sigma^0(\omega)^{-1} x_0^q = c_0 + \omega^{-1} \tau(x_0) - \omega^{-1} x_0^q \in A[T]$$

because  $\tau(x_0) \equiv x_0^q \mod \omega A[T]$ . Further from  $x_{i+1} = c_i + \omega^{-1} \tau(x_i)$  we find

$$a_{i+1}^{-1}x_{i+1} = \omega\sigma(\omega)\ldots\sigma^{i}(\omega)c_{i} + \sigma(\omega)\ldots\sigma^{i}(\omega)\tau(x_{i}) = \omega^{i+1}d_{i} + \tau(a_{i}^{-1}x_{i})$$

for a certain  $d_i \in A[T]$ , and hence

$$a_{i+1}^{-q} x_{i+1}^{q} = \tau(a_{i}^{-q} x_{i}^{q}) + \omega^{i+2} e_{i}$$
 (5.24)

for a certain  $e_i \in A[T]$ . It follows that

$$\begin{aligned} y_{i+1} - \omega^{-1} \tau(y_i) &= x_{i+2} - \sigma^{i+1}(\omega)^{-1} a_{i+1} a_{i+1}^{-q} x_{i+1}^q - \omega^{-1} \tau(x_{i+1}) \\ &+ \omega^{-1} \tau \left( \sigma^i(\omega)^{-1} a_i a_i^{-q} x_i^q \right) \\ &= c_{i+1} - \sigma^{i+1}(\omega)^{-1} \left( a_{i+1} a_{i+1}^{-q} x_{i+1}^q - \omega^{-1} \sigma(a_i) \tau(a_i^{-q} x_i^q) \right) \\ &= c_{i+1} - \sigma^{i+1}(\omega)^{-1} a_{i+1} \left( a_{i+1}^{-q} x_{i+1}^q - \tau(a_i^{-q} x_i^q) \right) \in A[T] \end{aligned}$$

because  $a_{i+1} = \omega^{-1} \sigma(a_i)$  and because of (5.24). (Recall that  $v(a_{i+1}) = -i - 1$  by (5.7).) This concludes the proof of Theorem 5.20.

- 6. Ramified Witt vectors and ramified Artin-Hasse exponentials. We keep the assumptions and notations of §5.
- 6.1. A preliminary Artin-Hasse exponential. Let B be an A-algebra which is A-torsion free and which admits an endomorphism  $\tau$ :  $B \otimes_A K \to B \otimes_A K$  which restricts to  $\sigma$  on  $A \otimes_A K = K \subset B \otimes_A K$  and which is such that  $\tau(b) \equiv b^q \mod \omega B$ . We define a map  $\Delta_B$ :  $B \to C_a(F; B)$  as follows.

$$\Delta_B(b) = f^{-1} \left( \sum_{i=0}^{\infty} \tau^i(b) a_i t^{q^i} \right).$$
 (6.2)

This is well defined by part (iii) of the Functional Equation Lemma. A quick check by means of (5.14)–(5.16) shows that  $\Delta_B$  is a homomorphism of A-algebras such that, moreover,

$$\Delta_{B} \circ \tau = \mathbf{f}_{\omega} \circ \Delta_{B} \tag{6.3}$$

(because  $\sigma^i(\omega)a_{i+1}=a_i$ ), and that  $\Delta_B$  is functorial in the sense that if  $(B',\tau')$  is a second such A-algebra with endomorphism  $\tau'$  of  $B'\otimes_A K$  and  $\phi\colon B\to B'$  is an A-algebra homomorphism such that  $\tau'\phi=\phi\tau$ , then  $C_q(F;\phi)\circ\Delta_B=\Delta_{B'}\circ\phi$ .

- 6.4. Remark. Using  $(B, \tau)$  instead of  $(A, \sigma)$  we can view F(X, Y) as a twisted Lubin-Tate formal B-module over B, if we are willing to extend the definition a bit, because, of course, B need not be a discrete valuation ring, nor is  $B \otimes_A K$  necessarily the quotient field of B. In fact B need not even be an integral domain. If we view F(X, Y) in this way then  $\Delta_B \colon B \to C_q(F; B)$  is just the B-algebra structure map of  $C_q(F; B)$ .
- 6.5. Now let B be any A-algebra. Then  $C_q(F; B)$  is an A-algebra which admits an endomorphism  $\tau$ , viz.  $\tau = \mathbf{f}_{\omega}$ , which, as  $\tau x \equiv x^q \mod \omega$  by (5.22), satisfies the hypotheses of 6.1 above (because  $\mathbf{f}_{\omega}$  is  $\sigma$ -semilinear). It is also immediate from

(5.10) and (5.4), cf. also (5.14), that  $C_q(F; B)$  is always A-torsion free. Substituting  $C_q(F; B)$  for B in 6.1 we therefore find A-algebra homomorphisms  $E_B: C_q(F; B) \to C_q(F; C_q(F; B))$  which are functorial in B because  $\mathbf{f}_{\omega}$  is functorial, and because of the functoriality property of the  $\Delta_B$  mentioned in 6.1 above. This functorial A-algebra homomorphism is in fact the ramified Artin-Hasse exponential we are seeking and, as is shown by the next theorem,  $C_q(F; B)$  is the desired ramified-Witt-vector functor.

6.6. THEOREM. Let A be complete with perfect residue field k. Let B be the ring of integers in a finite unramified extension L of K. Let l be the residue field of B. Consider the composed map

$$\mu_B: B \xrightarrow{\Delta_B} C_a(F; B) \to C_a(F; l).$$

Then  $\mu_B$  is an isomorphism of A-algebras. Moreover if  $\tau: B \to B$  is the unique extension of  $\sigma: A \to A$  such that  $\tau(b) \equiv b^q \mod B$ , then  $\mathbf{f}_{\omega}\mu_B = \mu_B \tau$ , i.e.  $\tau$  and  $\mathbf{f}_{\omega}$  correspond under  $\mu_B$ .

**PROOF.** Let  $b \in B$ . Consider  $\Delta_B(\omega'b)$ . Then from (6.2) we see that

$$f(\Delta_B(\omega'b)) \equiv a_r \tau'(\omega') \tau'(b) t^{q'} \mod(\omega B, \text{ degree } q^{r+1}).$$

By part (iv) of the Functional Equation Lemma 2.7 it follows that

$$\Delta_B(\omega'b) \equiv y_r \tau'(b) t^{q'} \mod(\omega B, \text{ degree } q^{r+1})$$

where  $y_r = a_r \tau'(\omega')$  is a unit of B. It follows that  $\mu_B$  maps the filtration subgroups  $\omega'B$  of B into the filtration subgroups  $C_a^{(r)}(F; l)$  and that the induced maps

$$l \stackrel{\sim}{\to} \omega^r B / \omega^{r+1} B \stackrel{\mu_B}{\to} C_q^{(r)}(F; l) / C_q^{(r+1)}(F; l) \stackrel{\sim}{\to} l$$

are given by  $x\mapsto y_r x^{q'}$  for  $x\in l$ . (Here  $l\stackrel{\sim}{\to}\omega'B/\omega^{r+1}B$  is induced by  $\omega'b\mapsto \bar{b}$  with  $\bar{b}$  the image of b in l under the canonical projection  $B\to l$ , and  $C_q^{(r)}(F;l)/C_q^{r+1}(F;l)\stackrel{\sim}{\to} l$  is induced by  $C_q^{(r)}(F;l)\to l$ ,  $\gamma(t)\mapsto$  (coefficient of  $t^{q'}$  in  $\gamma(t)$ ).) Because l is perfect and  $\bar{y}_r\neq 0$ , it follows that the induced maps  $\bar{\mu}_B$  are all isomorphisms. Hence  $\mu_B$  is an isomorphism because B and  $C_q(F;l)$  are both complete in their filtration topologies. The map  $\mu_B$  is an A-algebra homomorphism because  $\Delta_B$  is an A-algebra homomorphism and  $C_q(F;-l)$  is an A-algebra-valued functor. Finally the last statement of Theorem 6.6 follows because both  $\tau$  and  $\mu_B^{-1}\mathbf{f}_\omega\mu_B$  extend  $\sigma$  and  $\tau(b)\equiv b^q\equiv \mu_B^{-1}\mathbf{f}_\omega\mu_B(b)$  mod  $\omega B$ .

6.7. The maps  $s_{q,n}$  and  $w_{q,n}^F$ . The last thing to do is to reformulate the definitions of  $C_q(F; B)$  and  $E_B$  in such a way that they more closely resemble the corresponding objects in the unramified case, i.e. in the case of the ordinary Witt vectors. This is easily done, essentially because  $C_q(F; -)$  is representable.

Indeed, let, as a set-valued functor,  $W_{a,\infty}^F$ : Alg<sub>A</sub>  $\rightarrow$  Set be defined by

$$W_{q,\infty}^{F}(B) = \{(b_0, b_1, b_2, \dots) | b_i \in B\},$$

$$W_{q,\infty}^{F}(\phi)(b_0, b_1, \dots) = (\phi(b_0), \phi(b_1), \dots). \tag{6.8}$$

We now identify the set-valued functors  $W_{q,\infty}^F(-)$  and  $C_q(F;-)$  by the functorial isomorphism

$$e_B(b_0, b_1, \dots) = \sum_{i=0}^{\infty} {}^F b_i t^{q^i},$$
 (6.9)

and define  $W_{q,\infty}^F(-)$  as an A-algebra-valued functor by transporting the A-algebra structure on  $C_q(F; B)$  via  $e_B$  for all  $B \in \mathbf{Alg}_B$ . We use  $\mathbf{f}$  and  $\mathbf{V}$  to denote the endomorphisms of  $W_{q,\infty}^F(-)$  obtained by transporting  $\mathbf{f}_{\omega}$  and  $\mathbf{V}_q$  via  $e_B$ . Then one has immediately that

$$V(b_0, b_1, \dots) = (0, b_0, b_1, \dots)$$
(6.10)

and in fact

$$\mathbf{f}(b_0, b_1, \dots) = (\hat{b_0}, \hat{b_1}, \dots) \Rightarrow \hat{b_i} \equiv b_i^q \bmod \omega B. \tag{6.11}$$

(We have not proved the analog of this for  $f_{\omega}$ ; this is not difficult to do by using part (iv) of the Functional Equation Lemma and the additivity of  $f_{\omega}$ .)

Next we discuss the analog of the Witt polynomials  $X_0^{p^n} + pX_1^{p^{n-1}} + \cdots + p^nX_n$ . We define for the universal curve  $\gamma_T(t) \in C_o(F; A[T])$ ,

$$s_{a,n}(\gamma_T(t)) = a_n^{-1}(\text{coefficient of } t^{q^n} \text{ in } f(\gamma_T(t)))$$
 (6.12)

and, as usual, this is extended functorially for arbitrary curves  $\gamma(t)$  over arbitrary A-algebras by

$$s_{a,n}\gamma(t) = \phi(s_{a,n}(\gamma_T(t))) \tag{6.13}$$

where  $\phi: A[T] \to B$  is the unique A-algebra homomorphism such that  $\phi_* \gamma_T(t) = \gamma(t)$ . If B is A-torsion free one has, of course, the result that  $s_{q,n} \gamma(t) = a_n^{-1}$  (coefficient of  $t^{q^n}$  in  $f(\gamma(t))$ ). Using this one checks that

$$s_{q,n}(\gamma(t) + {}_{F}\delta(t)) = s_{q,n}(\gamma(t)) + s_{q,n}(\delta(t)),$$

$$s_{q,n}(\gamma(t) * \delta(t)) = s_{q,n}(\gamma(t))s_{q,n}(\delta(t)),$$

$$s_{q,n}(\{a\}_{F}\gamma(t)) = \sigma^{n}(a)s_{q,n}(\gamma(t)),$$

$$s_{q,n}(\mathbf{f}_{\omega}\gamma(t)) = s_{q,n+1}(\gamma(t)),$$

$$s_{q,n}(\mathbf{V}_{q}\gamma(t)) = \sigma^{n-1}(\omega)s_{q,n-1}(\gamma(t)) \text{ if } n > 1,$$

$$s_{q,0}(\mathbf{V}_{q}\gamma(t)) = 0,$$

$$s_{q,n}(t) = 1 \text{ for all } n. \tag{6.14}$$

Now suppose that we are in the situation of 6.1 above. Then, by the definition of  $\Delta_B$ , we have

$$s_{q,n}(\Delta_B(b)) = \tau^n(b). \tag{6.15}$$

Now define  $w_{q,n}^F(B)$ :  $W_{q,\infty}^F(B) \to B$  by  $w_{q,n}^F = s_{q,n} \circ e_B$ . It is not difficult to calculate  $w_{q,n}^F$ . Indeed

$$f(\gamma_T(t)) = f\left(\sum_{i=0}^{\infty} {}^F T_i t^{q^i}\right) = \sum_{j=0}^{\infty} \sum_{i=0}^{\infty} a_j T_i^j t^{q^{i+j}} = \sum_{r=0}^{\infty} \left(\sum_{i=0}^r a_i T_{r-i}^{q^i}\right) t^{q^r}$$

and it follows that  $w_{q,n}^F$  is the functorial map  $W_{q,\infty}^F(B) \to B$  defined by the polynomials

$$w_{q,n}^{F}(Z_{0}, \dots, Z_{n}) = a_{n}^{-1} \left( \sum_{i=0}^{n} a_{i} Z_{n-i}^{q^{i}} \right)$$

$$= Z_{0}^{q^{n}} + \sigma^{n-1}(\omega) Z_{1}^{q^{n-1}} + \sigma^{n-1}(\omega) \sigma^{n-2}(\omega) Z_{2}^{q^{n-2}} + \cdots$$

$$+ \sigma^{n-1}(\omega) \cdots \sigma(\omega) \omega Z_{n}. \tag{6.16}$$

- 6.17. THEOREM. Let  $(A, \sigma)$  be a pair consisting of a discrete valuation ring A of residue characteristic p > 0 and a Frobenius-like automorphism  $\sigma: K \to K$  such that (2.2) holds for some power q of p. Let  $\omega$  be any uniformizing element of A, and let  $w_{q,n}^F(Z)$ ,  $n = 0, 1, \ldots$  be the polynomials defined by (6.16). Then there exists a unique A-algebra-valued functor  $W_{q,\infty}^F$ :  $\mathbf{Alg}_A \to \mathbf{Alg}_A$  such that
- (i) as a set-valued functor  $W_{q,\infty}^F(B) = \{(b_0, b_1, b_2, \dots) | b_i \in B\}$  and  $W_{q,\infty}^F(\phi)(b_0, b_1, \dots) = (\phi(b_0), \phi(b_1), \dots)$  for all  $\phi: B \to B'$  in  $Alg_A$ ,
- (ii) the polynomials  $w_{q,n}^F(Z)$  induce functorial  $\sigma^n$ -semilinear A-algebra homomorphisms  $w_{q,\infty}^F\colon W_{q,\infty}^F(B)\to B, (b_0,b_1,\ldots)\mapsto w_{q,n}^F(b_0,\ldots,b_n)$ . Moreover, the functor  $W_{q,\infty}^F(-)$  has a  $\sigma^{-1}$ -semilinear A-module functor endomor-

Moreover, the functor  $W_{q,\infty}^F(-)$  has a  $\sigma^{-1}$ -semilinear A-module functor endomorphism V and a functorial  $\sigma$ -semilinear A-algebra endomorphism f which satisfy and are characterized by

(iii) 
$$w_{q,n}^F \circ \mathbf{V} = \sigma^{n-1}(\omega) w_{q,n-1}^F$$
 if  $n = 1, 2, ...; w_{q,0}^F \circ \mathbf{V} = 0$ , (iv)  $w_{q,n}^F \circ \mathbf{f} = w_{q,n+1}^F$ .

These endomorphisms f and V have (among others) the properties

- (v)  $\mathbf{fV} = \omega$ ,
- (vi)  $\mathbf{f}b \equiv b^q \mod \omega W_{q,\infty}^F(B)$  for all  $\mathbf{b} \in W_{q,\infty}^F(B)$ ,  $B \in \mathbf{Alg}_A$ ,
- (vii) V(b(fc)) = (Vb)c for all  $b, c \in W_{q,\infty}^F(B), B \in Alg_A$ .

Further there exists a unique functorial A-algebra homomorphism

$$E: W_{q,\infty}^F(-) \to W_{q,\infty}^F(W_{q,\infty}^F(-))$$

which satisfies and is characterized by

- (viii)  $w_{q,n}^F \circ E = \mathbf{f}^n$  for all  $n = 0, 1, 2, \ldots$  (Here  $w_{q,n}^F$ :  $W_{q,\infty}^F(W_{q,\infty}^F(B)) \to W_{q,\infty}^F(B)$  is short for  $w_{q,n,w_{q,\infty}^F(B)}^F$ , i.e. it is the map which assigns to a sequence  $(\mathbf{b}_0, \mathbf{b}_1, \ldots)$  of elements of  $W_{q,\infty}^F(B)$  the element  $w_{q,n}^F(\mathbf{b}_0, \mathbf{b}_1, \ldots) \in W_{q,\infty}^F(B)$ .) The functor homomorphism E further satisfies
- (ix)  $W_{q,\infty}^F(w_{q,n}^F) \circ E = \mathbf{f}^n$ , where  $W_{q,\infty}^F(w_{q,n}^F)$ :  $W_{q,\infty}^F(W_{q,\infty}^F(B)) \to W_{q,\infty}^F(B)$  assigns to a sequence  $(\mathbf{b}_0, \mathbf{b}_1, \dots)$  of elements of  $W_{q,\infty}^F(B)$  the sequence  $(w_{q,n}^F(\mathbf{b}_0), w_{q,n}^F(\mathbf{b}_1), \dots)$   $\in W_{q,\infty}^F(B)$ .

Finally if A is complete with perfect residue field k and l/k is a finite separable extension, then  $W_{q,\infty}^F(l)$  is the ring of integers B of the unique unramified extension L/K covering the residue field extension l/k and under this A-algebra isomorphism  $\mathbf{f}$  corresponds to the unique extension of  $\sigma$  to  $\tau\colon B\to B$  which satisfies  $\tau(b)\equiv b^q \mod \omega B$ . In particular  $W_{q,\infty}^F(k)\simeq A$  with  $\mathbf{f}$  corresponding to  $\sigma$ .

PROOF. Existence of  $W_{q,\infty}^F(-)$ , V, f, E such that (i), (ii), (iii), (iv), (viii) hold follows from the constructions above. Uniqueness follows because (i), (ii), (iii), (iv),

(viii) determine the A-algebra structure on  $B^{N\cup\{0\}}$ , V, f, E uniquely for A-torsion free A-algebras B, and then these structure elements are uniquely determined by (i)-(iv), (viii) for all A-algebras, by the functoriality requirement (because for every A-algebra B there exists an A-torsion free A-algebra B' together with a surjective A-algebra homomorphism  $B' \to B$ ). Of the remaining identities some have already been proved in the  $C_q(F; -)$ -setting ((v) and (vi)). They can all be proved by checking that they give the right answers whenever composed with the  $w_{q,n}^F$ . This proves that they hold over A-torsion free algebras B, and then they hold in general by functoriality. So to prove (vii) we calculate

$$w_{q,0}^F(\mathbf{V}(\mathbf{b}(\mathbf{fc}))) = 0,$$

$$w_{q,n}^F(\mathbf{V}(\mathbf{b}(\mathbf{fc}))) = \sigma^{n-1}(\omega)w_{q,n-1}^F(\mathbf{b}(\mathbf{fc})) = \sigma^{n-1}(\omega)w_{q,n-1}^F(\mathbf{b})w_{q,n-1}^F(\mathbf{fc})$$

$$= \sigma^{n-1}(\omega)w_{q,n-1}^F(\mathbf{b})w_{q,n}^F(\mathbf{c})$$

and, on the other hand,

$$w_{q,0}^{F}((\mathbf{V}\mathbf{b})\mathbf{c}) = w_{q,0}^{F}(\mathbf{V}\mathbf{b})w_{q,0}^{F}(\mathbf{c}) = 0, \quad w_{q,0}^{F}(\mathbf{c}) = 0,$$
  
$$w_{q,n}^{F}((\mathbf{V}\mathbf{b})\mathbf{c}) = w_{q,n}^{F}(\mathbf{V}\mathbf{b})w_{q,n}^{F}(\mathbf{c}) = \sigma^{n-1}(\omega)w_{q,n-1}^{F}(\mathbf{b})w_{q,n}^{F}(\mathbf{c}).$$

This proves (vii). To prove (ix) we proceed similarly.

$$w_{q,m}^F \circ W_{q,\infty}^F(w_{q,n}^F) \circ E = w_{q,n}^F \circ w_{q,m}^F \circ E = w_{q,n}^F \circ \mathbf{f}^m = w_{q,n+m}^F = w_{q,m}^F \circ \mathbf{f}^n$$

(Here the first equality follows from the functoriality of the morphisms  $w_{q,m}^F$  which says that for all  $\phi: B' \to B \in \mathbf{Alg}_A$  we have  $w_{q,m}^F \circ W_{q,\infty}^F(\phi) = \phi \circ w_{q,m}^F$ ; now substitute  $w_{q,n}^F$  for  $\phi$ .)

6.18. REMARK. Vf = fV does not, of course, hold in general (also not in the case of the usual Witt vectors). It is, however, true in  $W_{q,\infty}^F(B)$  if  $\omega B = 0$ , as easily follows from (6.11), which implies that  $\mathbf{f}(b_0, b_1, \ldots) = (b_0^q, b_1^q, \ldots)$  if  $\omega B = 0$ .
