RELATIONS BETWEEN H_u^p AND L_u^p WITH POLYNOMIAL WEIGHTS

BY

JAN-OLOV STRÖMBERG AND RICHARD L. WHEEDEN¹

ABSTRACT. Relations between L_u^p and H_u^p of the real line are studied in the case when $p > 1$ and $u(x) = |q(x)|^p w(x)$, where $q(x)$ is a polynomial and $w(x)$ satisfies the A_p condition. It turns out that H_u^p and L_u^p can be identified when all the zeros of q are real, and that otherwise H_u^p can be identified with a certain proper subspace of L_u^p . In either case, a complete description of the distributions in H_u^p is given. The questions of boundary values and of the existence of dense subsets of smooth functions are also considered.

1. Introduction. In this paper, we study relations between L_u^p and H_u^p of the real line, where $1 < p < \infty$, $u = u(x)$ is a nonnegative weight function,

$$L_u^p = \left\{ f: \left(\int_{\mathbf{R}} |f(x)|^p u(x) dx \right)^{1/p} < \infty \right\},$$

and H_u^p is the corresponding Hardy space. To define H_u^p precisely, let $\mathcal{S}$ be the Schwartz space of rapidly decreasing functions, $\mathcal{S}'$ be the space of tempered distributions, and for $l \in \mathcal{S}'$, let Ml denote the nontangential maximal function defined by

$$Ml(x) = (M_{\gamma, \phi} l)(x) = \sup_{(\xi, t) \in \Gamma_\gamma(x)} |\langle l, \phi_t(\xi - \cdot) \rangle|,$$

where $\Gamma_\gamma(x)$ is the cone in $\mathbf{R}_+^2$ of points (ξ, t) with $|x - \xi| < \gamma t$, $\gamma > 0$, $\phi \in \mathcal{S}$, $\phi_t(x) = t^{-1} \phi(x/t)$, $t > 0$, and $\langle l, \psi \rangle$ denotes the action of l on ψ . Then H_u^p is defined to be the collection of $l \in \mathcal{S}'$ such that $M_{\gamma, \phi} l \in L_u^p$ for some $\gamma > 0$ and some ϕ with $\int_{\mathbf{R}} \phi dx \neq 0$. If u merely satisfies the doubling condition $\int_{2I} u dx \leq c \int_I u dx$, where I is an interval, $2I$ is its double and c is a constant independent of I , then the condition that $l \in H_u^p$ is known to be independent of any particular $\gamma > 0$ or $\phi \in \mathcal{S}$ with $\int_{\mathbf{R}} \phi dx \neq 0$ (see [9]). We will use the notations

$$\|f\|_{L_u^p} = \|f\|_{p, u} = \left(\int_{\mathbf{R}} |f|^p u dx \right)^{1/p}$$

Received by the editors September 30, 1980. The results were presented at the A.M.S. Summer Meeting (August, 1980) in Ann Arbor, Michigan.

and

$$\|l\|_{H_u^p} = \|M_{\gamma, \phi} l\|_{p, u},$$

for some fixed choice of γ and ϕ , $\int_{\mathbf{R}} \phi \, dx \neq 0$.

If u satisfies the A_p condition

$$\left(\frac{1}{|I|} \int_I u(x) \, dx \right) \left(\frac{1}{|I|} \int_I u(x)^{-1/(p-1)} \, dx \right)^{p-1} \leq c, \quad 1 < p < \infty,$$

where c is independent of I , then H_u^p and L_u^p can be identified in the sense that every $f \in L_u^p$ generates a distribution $l_f \in H_u^p$ defined by $\langle l_f, \phi \rangle = \int_{\mathbf{R}} f(x) \phi(x) \, dx$, $\phi \in \mathcal{S}$, and to every $l \in H_u^p$, there corresponds a unique $f \in L_u^p$ such that $l = l_f$. Moreover, in this correspondence, $\|f\|_{L_u^p}$ and $\|l\|_{H_u^p}$ are equivalent. These results are well-known corollaries of the fact (see [6]) that the transformation $f \rightarrow f^*$, where f^* denotes the Hardy-Littlewood maximal function of f , is bounded on L_u^p , $1 < p < \infty$, if $u \in A_p$.

The weights u considered in this paper for L_u^p and H_u^p will belong to A_r for some $r > p$ but will not belong to A_p . Their specific form is $u(x) = |q(x)|^p w(x)$ where q is a polynomial and $w \in A_p$. Thus, u may have zeros of large orders, and consequently, functions in L_u^p are not generally locally integrable. The motivation for considering such u stems from several places. First, they arise in [8] in multiplier questions for L_u^p . Since multiplier results are also derived in [9] for H_u^p , we wished to relate L_u^p and H_u^p for this type of u .

As further motivation for studying such u , let us consider a variant of the Hilbert transform. We introduce this variant only for illustration since our proofs do not require any facts about Hilbert transforms. Let $u = |q|^p w$ where q is a polynomial, $1 < p < \infty$, and $w \in A_p$, and define

$$(1.1) \quad H_q f(x) = \text{p.v.} \int_{\mathbf{R}} f(z) \left[\frac{1}{x-z} - \frac{1}{q(x)} \frac{q(x) - q(z)}{x-z} \right] dz.$$

The identity

$$\frac{1}{x-z} - \frac{1}{q(x)} \frac{q(x) - q(z)}{x-z} = \frac{1}{q(x)} \frac{q(z)}{x-z}$$

shows that $H_q f(x) = (fq)^{\sim}(x)/q(x)$, where “ $\sim$ ” denotes the ordinary Hilbert transform. Hence, by the principal result of [4], since $w \in A_p$, we have

$$\|H_q f\|_{p, u} = \|(fq)^{\sim}\|_{p, w} \leq c \|fq\|_{p, w} = c \|f\|_{p, u};$$

that is, H_q is bounded on L_u^p .

Next note that if q has degree M , then $(q(x) - q(z))/(x - z)$ is a polynomial in z of degree $M - 1$. Hence, if the first M moments of f exist and equal zero, i.e., if

$$(1.2) \quad \int_{\mathbf{R}} f(z) z^i \, dz = 0, \quad i = 0, \dots, M-1,$$

it follows that $H_q f = \tilde{f}$. Condition (1.2) is clearly satisfied for any M if f belongs to the space $\mathcal{S}_{0,0}$ of functions in $\mathcal{S}$ whose Fourier transforms have compact support not containing the origin. Conversely, a result of E. Adams [1] states that if u satisfies

the doubling condition and the mapping $f \rightarrow \tilde{f}$ satisfies $\|\tilde{f}\|_{p,u} \leq c\|f\|_{p,u}$ for all $f \in \mathcal{S}_{0,0}$, then u must have the form $u = |q|^p w$ where q is a polynomial and $w \in A_p$. Thus, in a sense, such u are the only weights for which the Hilbert transform is bounded. This can be used to show that if u satisfies A_r for any r and the mapping $f \rightarrow Mf$ satisfies $\|Mf\|_{p,u} \leq c\|f\|_{p,u}$ for all $f \in \mathcal{S}_{0,0}$, i.e., if

$$(1.3) \quad \|f\|_{H_u^p} \leq c\|f\|_{L_u^p}, \quad f \in \mathcal{S}_{0,0},$$

then u must have the form above. In fact, the norm boundedness of Mf implies that of the usual (harmonic) Lusin area integral Sf , and since $Sf = S\tilde{f}$, also of $M\tilde{f}$ (see [3, 9]). Since $M\tilde{f}$ pointwise exceeds $|\tilde{f}|$, it follows that the assumptions of Adams' result hold, and therefore that u has the desired form.

The fact that H_q is bounded on L_u^p for such u makes it reasonable to conjecture that L_u^p and H_u^p should coincide. This, however, is not generally the case. The key point to consider turns out to be whether or not all the zeros of q are real. We will systematically use the notation $Q(x)$ to denote a polynomial all of whose zeros are real. The degree of Q will always be denoted N and its distinct zeros will be $\{a_k\}_{k=1}^n$. We normalize Q so that

$$Q(x) = \prod_{k=1}^n (x - a_k)^{\mu_k},$$

μ_k being the order (multiplicity) of the zero at a_k . Associated with the partial fraction decomposition of $1/Q$, namely

$$(1.4) \quad \frac{1}{Q(x)} = \sum_{k=1}^n \sum_{l=1}^{\mu_k} \frac{A_{k,l}}{(x - a_k)^l},$$

will be the distribution

$$(1.5) \quad \mathfrak{D} = \mathfrak{D}^Q = \sum_{k=1}^n \sum_{l=1}^{\mu_k} \frac{A_{k,l}}{(l-1)!} \delta_{a_k}^{(l-1)},$$

where $\delta_a^{(i)}$ denotes the i th derivative of the delta function at a . $\mathfrak{D}$ is of course supported at the a_k 's. If $F(x, y)$ is a function, $\mathfrak{D}_y F$ will denote the action of $\mathfrak{D}$ on F as a function of y . It follows directly from (1.4) and (1.5) that

$$\mathfrak{D}_y^Q(1/(x - y)) = 1/Q(x).$$

If ϕ is a function whose derivatives of order $\mu_k - 1$ exist at a_k , $k = 1, \dots, n$, define

$$(1.6) \quad \mathfrak{P}_\phi(x) = \mathfrak{P}_\phi^Q(x) = Q(x) \mathfrak{D}_y^Q(\phi(y)/(x - y)).$$

We will discuss the principal properties of $\mathfrak{P}$ in the next two sections. Here, we mention that $\mathfrak{P}$ is a polynomial in x whose first $\mu_k - 1$ derivatives at a_k coincide with the corresponding derivatives of ϕ at a_k . Such a polynomial is called an interpolating polynomial; rather than trying to deduce its properties from known facts, we will give direct derivations based on (1.6).

We introduce $\mathfrak{P}$ in order to consider modified convolution operators

$$\int_{\mathbf{R}} f(z) [\phi(x - z) - \mathfrak{P}_{\phi(x-\cdot)}^Q(z)] dz.$$

Our motivation again comes from the Hilbert transform. In fact, the term subtracted in (1.1) from the usual kernel $1/(x - z)$ of the Hilbert transform may be written

$$\begin{aligned} \frac{1}{Q(x)} \frac{Q(x) - Q(z)}{x - z} &= \frac{Q(z)}{x - z} \left[\frac{1}{Q(z)} - \frac{1}{Q(x)} \right] \\ &= \frac{Q(z)}{x - z} \left[\mathfrak{O}_y \left(\frac{1}{z - y} \right) - \mathfrak{O}_y \left(\frac{1}{x - y} \right) \right] \\ &= \frac{Q(z)}{x - z} \mathfrak{O}_y \left(\frac{x - z}{(z - y)(x - y)} \right) \\ &= Q(z) \mathfrak{O}_y \left(\frac{1/(x - y)}{z - y} \right) = \mathfrak{P}_{1/(x - \cdot)}^Q(z). \end{aligned}$$

Our main results for the case when q has only real zeros are given in the following two theorems.

THEOREM 1. *Let $1 < p < \infty$, Q be a polynomial of degree N with all real zeros, and*

$$f(x, t) = \int_{\mathbf{R}} f(z) \left[\phi_t(x - z) - \mathfrak{P}_{\phi_t(x - \cdot)}^Q(z) \right] dz,$$

where $(1 + |x|)^{\alpha+1} |\phi^{(\alpha)}(x)|$ is bounded for $\alpha = 0, \dots, N$. If

$$N_\lambda f(x) = \sup_{(\xi, t) \in \mathbf{R}_+^2} \left(\frac{t}{t + |x - \xi|} \right)^\lambda |f(\xi, t)|,$$

then for $\lambda \geq N + 1$, $\lambda > 1$, there is a constant c independent of f such that $\|N_\lambda f\|_{p,u} \leq c \|f\|_{p,u}$, where $u = |Q|^p w$, $w \in A_p$. In particular, the nontangential maximal function Mf satisfies $\|Mf\|_{p,u} \leq c \|f\|_{p,u}$.

We will also prove a weak-type version of this result when $p = 1$.

THEOREM 2. *Let $1 < p < \infty$ and $u = |Q|^p w$ where Q is a polynomial with all real zeros and $w \in A_p$. Then H_u^p and L_u^p can be identified in the following sense: there is a unique correspondence between distributions $l \in H_u^p$ and functions $f \in L_u^p$ given by*

$$\langle l, \phi \rangle = \int_{\mathbf{R}} f(z) [\phi(z) - \mathfrak{P}_\phi^Q(z)] dz, \quad \phi \in \mathfrak{S}.$$

Moreover, in this correspondence $\|l\|_{H_u^p}$ and $\|f\|_{L_u^p}$ are equivalent.

As a corollary of Theorem 2, we see that the $H_{|Q|^p w}^p$ norm of f is equivalent to the H_w^p norm of fQ . We will also show directly in §6 that the function

$$f(x, t) = \langle l_f, \phi_t(x - \cdot) \rangle$$

converges pointwise almost everywhere and in L_u^p norm to f as $t \rightarrow 0$.

If q has d complex roots, counting multiplicities, then

$$c_1 \leq |q(x)| / (1 + |x|^2)^{d/2} |Q(x)| \leq c_2$$

for positive constants c_1 and c_2 , where Q contains all the real zeros of q . Hence, we may assume without loss of generality that

$$u(x) = (1 + |x|^2)^{d/2} |Q(x)|^p w(x).$$

Again using the Hilbert transform for motivation, note that if $q = q_1 Q$ where q_1 has degree $d \geq 1$, then

$$\frac{1}{q(x)} \frac{q(x) - q(z)}{x - z} = \frac{1}{Q(x)} \frac{Q(x) - Q(z)}{x - z} + \frac{1}{q(x)} Q(z) \frac{q_1(x) - q_1(z)}{x - z}.$$

Since $(q_1(x) - q_1(z))/(x - z)$ is a polynomial in z of degree $d - 1$, the second term on the right is the sum of terms of the form $c_i(x)Q(z)z^i$, $i = 0, \dots, d - 1$. It follows that if

$$(1.7) \quad \int_{\mathbf{R}} f(z)Q(z)z^i dz = 0, \quad i = 0, \dots, d - 1,$$

then

$$H_q f(x) = \text{p.v.} \int_{\mathbf{R}} f(z) \left[\frac{1}{x - z} - \frac{1}{Q(x)} \frac{Q(x) - Q(z)}{x - z} \right] dz = H_Q f(x).$$

Thus, H_Q is bounded on the subset of L_u^p of functions f satisfying (1.7). This subset can be identified with H_u^p as the following result states.

THEOREM 3. *Let $1 < p < \infty$, d be a positive integer and $u = (1 + |x|^2)^{dp/2} |Q|^p w$, where Q is a polynomial with all real zeros and $w \in A_p$. Then H_u^p can be identified with the subspace of L_u^p of f with $\int_{\mathbf{R}} f Q x^i dx = 0$ for $i = 0, \dots, d - 1$. The identification is given by*

$$\langle l, \phi \rangle = \int_{\mathbf{R}} f(z) [\phi(z) - \mathfrak{P}_{\phi}^Q(z)] dz,$$

$l \in H_u^p$, $f \in L_u^p$, and $\|l\|_{H_u^p}$ is equivalent to $\|f\|_{L_u^p}$.

As a corollary of Theorem 3, we will see that the H^p norm of f with weight $u = (1 + |x|^2)^{dp/2} |Q|^p w$ is equivalent to the H^p norm of fQ with weight $(1 + |x|^2)^{dp/2} w$. We will also derive the general form for embeddings of L_u^p in H_u^p which are the identity on H_u^p .

In the last section of the paper, we prove several results about the density of $\mathfrak{S}_{0,0}$ in H_u^p . While our proofs are direct, we mention that some of the results can be obtained indirectly as corollaries of Theorems 2 and 3 and the density results in [9].

Finally, we list some notation and basic facts. From the definition of A_p , we have that $w \in A_p$, $1 < p < \infty$, if and only if $w^{-1/(p-1)} \in A_{p'}$, $1/p + 1/p' = 1$. Also, from [4], if $w \in A_p$ then

$$\int_{|x|>r} \frac{w(x)}{|x|^p} dx \leq \frac{c}{r^p} \int_{|x|<r} w(x) dx, \quad r > 0.$$

In particular, both $w(x)(1 + |x|)^{-p}$ and $w(x)^{-1/(p-1)}(1 + |x|)^{-p'}$ are integrable over $\mathbf{R}$ if $w \in A_p$. If I is an interval and $s > 0$, let sI denote the interval concentric with I whose length is $s|I|$. A weight u is said to satisfy the doubling condition of order $\beta > 0$ if there is a constant c independent of s such that $\int_{sI} u dx \leq cs^\beta \int_I u dx$, $s > 1$. It follows easily that any $w \in A_p$ satisfies this condition with $\beta = p$, and that any u of the form $u = |q|^p w$ where q has degree M and $w \in A_p$ satisfies it with $\beta = (M + 1)p$.

About H_u^p , we will use the fact that $\|N_\lambda I\|_{p,u} \leq c\|I\|_{H_u^p}$ if u satisfies the doubling condition of order β and $\lambda > \beta/p$. In particular, if $u \in A_p$, $1 < p < \infty$, the fact that H_u^p and L_u^p can be identified then shows that $\|N_\lambda f\|_{p,u} \leq c\|f\|_{p,u}$ if $\lambda > 1$. Finally, we will use the fact that if u satisfies any doubling condition, then a distribution l whose radial maximal function

$$M_0 l(x) = \sup_{t>0} |\langle l, \phi_t(x - \cdot) \rangle|$$

belongs to L_u^p for some $\phi \in \mathfrak{S}$ with $\int_{\mathbf{R}} \phi \, dx \neq 0$ also belongs to H_u^p . Proofs of these results may be found in [9].

2. Preliminaries. Let Q and $\mathfrak{D}$ be as in the introduction: that is, let $Q(x) = \prod_{k=1}^n (x - a_k)^{\mu_k}$, a_k real and distinct, $\sum_{k=1}^n \mu_k = N$, and let

$$\mathfrak{D} = \mathfrak{D}^Q = \sum_{k=1}^n \sum_{l=1}^{\mu_k} \frac{A_{k,l}}{(l-1)!} \delta_{a_k}^{(l-1)},$$

where $Q(x)^{-1} = \sum_{k=1}^n \sum_{l=1}^{\mu_k} (A_{k,l}/(x - a_k)^l)$. As noted in the introduction, we have

$$(2.1) \quad \mathfrak{D}_y((x - y)^{-1}) = (Q(x))^{-1}.$$

LEMMA (2.2).

(i) If P is a polynomial of degree M , then $\mathfrak{D}_y[(P(x) - P(y))/(x - y)]$ is a polynomial of degree at most $M - 1$.

(ii) If $\phi \in C^\infty$, then $\mathfrak{D}_y[(\phi(x) - \phi(y))/(x - y)] \in C^\infty$.

(iii) If $\phi \in C^\infty$ and $\mathfrak{B}$ is any distribution of the form $\mathfrak{B} = \sum_{k=1}^n \sum_{l=1}^{\mu_k} B_{k,l} \delta_{a_k}^{(l-1)}$, then $\mathfrak{B}(\phi Q) = 0$.

PROOF. (i) $(P(x) - P(y))/(x - y)$ is a polynomial in x, y of degree $M - 1$. Applying $\mathfrak{D}_y$ to it produces a polynomial in x of degree at most $M - 1$.

(ii) It is enough to show that $(\phi(x) - \phi(y))/(x - y)$ is infinitely differentiable on $\mathbf{R} \times \mathbf{R}$. This follows easily from the formula

$$\frac{\phi(x) - \phi(y)}{x - y} = \int_0^1 \phi'(y + s(x - y)) \, ds.$$

(iii) It is enough to show each $\delta_{a_k}^{(l-1)}(\phi Q) = 0$, $1 \leq l \leq \mu_k$. By Leibniz's rule,

$$\delta_{a_k}^{(l-1)}(\phi Q) = \sum_{j=0}^{l-1} \binom{l-1}{j} \phi^{(l-1-j)}(a_k) Q^{(j)}(a_k) = 0$$

since $Q^{(j)}(a_k) = 0$ for $0 \leq j \leq \mu_k - 1$.

LEMMA (2.3). If $\phi \in C^\infty$, then $Q(x) \mathfrak{D}_y[\phi(y)/(x - y)]$ is a polynomial of degree at most $N - 1$.

PROOF. It is enough to show that each $Q(x) \delta_{a_k,y}^{(l-1)}[\phi(y)/(x - y)]$, $1 \leq l \leq \mu_k$, $1 \leq k \leq n$, is a polynomial of degree at most $N - 1$. But $\delta_{a_k,y}^{(l-1)}[\phi(y)/(x - y)]$ is a linear combination of terms $(x - a_k)^{-i}$, $1 \leq i \leq l$, and since $Q(x)$ contains the factor $(x - a_k)^{\mu_k}$, the conclusion follows.

We use the notation $\mathfrak{P}_\phi(x) = \mathfrak{P}_\phi^Q(x) = Q(x)\mathfrak{D}_y^Q[\phi(y)/(x-y)]$ for the polynomial in Lemma (2.3). The next lemma shows that $\mathfrak{P}_\phi$ is the interpolating polynomial for ϕ based on Q .

LEMMA (2.4). *Let $\mathfrak{B}$ be any distribution of the form $\mathfrak{B} = \sum_{k=1}^n \sum_{l=1}^{\mu_k} B_{k,l} \delta_{a_k}^{(l-1)}$. If $\phi \in C^\infty$, then $\mathfrak{B}(\phi - \mathfrak{P}_\phi) = 0$.*

PROOF. We have

$$\begin{aligned}\phi(x) - \mathfrak{P}_\phi(x) &= \phi(x) - Q(x)\mathfrak{D}_y[\phi(y)/(x-y)] \\ &= Q(x)\mathfrak{D}_y[(\phi(x) - \phi(y))/(x-y)] = Q(x)\psi(x)\end{aligned}$$

for some $\psi \in C^\infty$, by (2.1) and Lemma (2.2)(ii). By Lemma (2.2)(iii), $\mathfrak{B}(Q\psi) = 0$, and the proof is complete.

Note that since $\mathfrak{P}_\phi$ has degree at most $N-1$, it is the only polynomial of degree at most $N-1$ with $\mathfrak{B}(\phi - \mathfrak{P}_\phi) = 0$ for all $\mathfrak{B}$ as above.

We now list properties of $\mathfrak{P}$ and $\mathfrak{D}$ which will be useful.

LEMMA (2.5).

(i) *If P is a polynomial of degree at most $N-1$, then $\mathfrak{D}_y[P(y)/(x-y)] = P(x)/Q(x)$. Equivalently, $\mathfrak{P}_P^Q(x) = P(x)$ for such P .*

(ii) $\mathfrak{P}_{\phi Q}^Q(x) = 0$ if $\phi \in C^\infty$.

PROOF. Part (i) follows immediately from the uniqueness of $\mathfrak{P}$ mentioned above. Part (ii) is similar, using Lemma (2.2)(iii).

LEMMA (2.6). *If $\phi \in \mathfrak{S}$ and Q has degree N , then for any z*

$$\int_{\mathbf{R}} [\phi(x-z) - \mathfrak{P}_{\phi(x-\cdot)}^Q(z)] x^j dx = 0, \quad j = 0, \dots, N-1.$$

PROOF. The integral may be written

$$Q(z)\mathfrak{D}_y \left\{ \int_{\mathbf{R}} [\phi(x-z) - \phi(x-y)] x^j dx / (z-y) \right\}.$$

We have $\int_{\mathbf{R}} \phi(x-z)x^j dx = \int_{\mathbf{R}} \phi(x)(x-z)^j dx = P(z)$, where P is a polynomial in z of degree at most j . The expression above then equals

$$Q(z)\mathfrak{D}_y \{ (P(z) - P(y)) / (z-y) \} = 0 \quad \text{if } j \leq N-1$$

by Lemma (2.5)(i).

Next, we list some relations between the $\mathfrak{D}$'s and $\mathfrak{P}$'s associated with $Q(x)$ and $xQ(x)$.

LEMMA (2.7). (i) *If $\phi \in C^\infty$, then $\mathfrak{D}^{xQ}(\phi) = \mathfrak{D}^Q[(\phi(y) - \phi(0))/y]$.*

(ii) *If $\phi \in C^\infty$, then $\mathfrak{P}_\phi^{xQ} = \mathfrak{P}_\phi^Q + \mathfrak{D}^{xQ}(\phi) \cdot Q$.*

PROOF. (i) Note that $(\phi(y) - \phi(0))/y = \int_0^1 \phi'(sy) ds$, so that $(\phi(y) - \phi(0))/y$ is also smooth and equals $\phi'(0)$ at $y=0$. Let $\tilde{\mathfrak{D}}(\phi) = \mathfrak{D}^Q[(\phi(y) - \phi(0))/y]$. Then both $\tilde{\mathfrak{D}}$ and $\mathfrak{D}^{xQ}$ are linear combinations of derivatives of delta functions. To show that $\tilde{\mathfrak{D}}(\phi) = \mathfrak{D}^{xQ}(\phi)$, it is then enough, using the uniqueness of partial fraction

decompositions, to show that $\tilde{\mathfrak{D}}_y[1/(x-y)] = \mathfrak{D}_y^{xQ}[1/(x-y)]$. However, by (2.1), $\mathfrak{D}_y^{xQ}[1/(x-y)] = 1/xQ(x)$, while

$$\begin{aligned}\tilde{\mathfrak{D}}_y\left(\frac{1}{x-y}\right) &= \mathfrak{D}_y^Q\left[\frac{1/(x-y) - 1/x}{y}\right] = \mathfrak{D}_y^Q\left[\frac{1}{x(x-y)}\right] \\ &= \frac{1}{x}\mathfrak{D}_y^Q\left(\frac{1}{x-y}\right) = \frac{1}{xQ(x)}\end{aligned}$$

by (2.1) again.

To prove (ii), write $x = (x-y) + y$ to obtain

$$x\mathfrak{D}_y^{xQ}\left(\frac{\phi(y)}{x-y}\right) = \mathfrak{D}_y^{xQ}\left(\frac{x\phi(y)}{x-y}\right) = \mathfrak{D}^{xQ}(\phi) + \mathfrak{D}_y^{xQ}\left(\frac{y\phi(y)}{x-y}\right).$$

By (i), the last term on the right equals $\mathfrak{D}_y^Q[\phi(y)/(x-y)]$, and (ii) follows immediately by multiplying the resulting identity by $Q(x)$.

By repeated application of formula (ii), we obtain for any positive integer d

$$(2.8) \quad \mathfrak{P}_\phi^{x^dQ}(z) = \mathfrak{P}_\phi^Q(z) + \sum_{j=0}^{d-1} \mathfrak{D}^{x^{j+1}Q}(\phi) \cdot z^j Q(z).$$

Finally, we list some relations between $\mathfrak{P}$ and ordinary Taylor polynomials.

LEMMA (2.9). *With the usual notation, the following formulas hold:*

$$\begin{aligned}(i) \quad & \mathfrak{P}_\phi^{(x-a)'}(z) = \sum_{i=0}^{l-1} \frac{\phi^{(i)}(a)}{i!} (z-a)^i; \\ (ii) \quad & \mathfrak{P}_\phi^Q(z) = Q(z) \sum_{k=1}^n \sum_{l=1}^{\mu_k} \frac{A_{k,l}}{(z-a_k)^l} \mathfrak{P}_\phi^{(x-a_k)'}(z); \\ (iii) \quad & \mathfrak{P}_\phi^Q(z) = P(z) + Q(z) \sum_{k=1}^n \sum_{l=1}^{\mu_k} \frac{A_{k,l}}{(z-a_k)^l} \mathfrak{P}_{\phi-P}^{(x-a_k)'}(z),\end{aligned}$$

where in (iii), $P(z)$ is any polynomial of degree at most $N-1$.

PROOF. By definition,

$$\mathfrak{P}_\phi^Q(z) = Q(z)\mathfrak{D}_y^Q\left(\frac{\phi(y)}{z-y}\right) = Q(z) \sum_{k=1}^n \sum_{l=1}^{\mu_k} \frac{A_{k,l}}{(l-1)!} \delta_{a_k,y}^{(l-1)} \left(\frac{\phi(y)}{z-y}\right).$$

Hence,

$$\mathfrak{P}_\phi^{(x-a)'}(z) = (z-a)^l \frac{1}{(l-1)!} \delta_{a,y}^{(l-1)} \left(\frac{\phi(y)}{z-y}\right),$$

and (i) follows by direct computation with Leibniz's rule. Part (ii) follows from the last two formulas by substituting the second into the first. To prove (iii), write $\phi = P + (\phi - P)$ to obtain $\mathfrak{P}_\phi^Q = \mathfrak{P}_P^Q + \mathfrak{P}_{\phi-P}^Q = P + \mathfrak{P}_{\phi-P}^Q$, since P has degree at most $N-1$. Applying (ii) to the last term on the right gives (iii).

Formula (iii) may be used to compare $\mathcal{P}_\phi^Q$ to any P of degree $\leq N - 1$. We will choose $P = \mathcal{P}_\phi^{x^N}$, the Taylor polynomial of ϕ of order $N - 1$ around the origin. The derivatives of a Taylor polynomial satisfy

$$\left(\mathcal{P}_\phi^{x^N}\right)^{(j)} = \mathcal{P}_{\phi^{(j)}}^{x^{N-j}}, \quad j = 0, \dots, N - 1,$$

which follows easily for $j = 1$ from (i) of the last lemma, and for $j > 1$ by repeated application of the case $j = 1$. Using this and (i) of the lemma, we have

$$\begin{aligned} \mathcal{P}_{\phi - \mathcal{P}_\phi^{x^N}}^{(x - a_k)^l}(z) &= \sum_{j=0}^{l-1} \frac{1}{j!} \left(\phi - \mathcal{P}_\phi^{x^N}\right)^{(j)}(a_k)(z - a_k)^j \\ &= \sum_{j=0}^{l-1} \frac{1}{j!} \left\{ \phi^{(j)}(a_k) - \mathcal{P}_{\phi^{(j)}}^{x^{N-j}}(a_k) \right\} (z - a_k)^j \\ &= \sum_{j=0}^{l-1} \frac{1}{j!} \left\{ \phi^{(j)}(a_k) - \sum_{i=0}^{N-j-1} \frac{1}{i!} \phi^{(j+i)}(0) a_k^i \right\} (z - a_k)^j. \end{aligned}$$

Hence, by (iii) of the lemma,

$$\begin{aligned} \mathcal{P}_\phi^Q(z) &= \sum_{j=0}^{N-1} \frac{\phi^{(j)}(0)}{j!} z^j + Q(z) \sum_{k=1}^n \sum_{l=1}^{\mu_k} \frac{A_{k,l}}{(z - a_k)^l} \\ (2.10) \quad &\cdot \sum_{j=0}^{l-1} \frac{1}{j!} \left\{ \phi^{(j)}(a_k) - \sum_{i=0}^{N-j-1} \frac{1}{i!} \phi^{(j+i)}(0) a_k^i \right\} (z - a_k)^j. \end{aligned}$$

3. Basic estimates. The main results of this section concern estimates for the interpolating polynomial $\mathcal{P}_{\phi, (x - \cdot)_t}(z)$ and the remainder $\phi_t(x - z) - \mathcal{P}_{\phi, (x - \cdot)_t}(z)$ which are uniform in $t > 0$. These estimates are given in Lemma (3.3). We will obtain tempered tangential (and therefore also nontangential) estimates as corollaries. Throughout this section, Q will denote a polynomial of degree N with only real zeros $\{a_k\}$ and $\mathcal{P}_\phi = \mathcal{P}_\phi^Q$. Moreover, by A_1 , we mean the class of weights w with $|I|^{-1} \int_I w \, dx \leq c \operatorname{ess}_I w$.

The following simple preliminary lemma will be useful later.

LEMMA (3.1). *If ϕ has N bounded derivatives and $c_\phi = \max_{j=0, \dots, N} \|\phi^{(j)}\|_\infty$, then*

$$|\phi(x) - \mathcal{P}_\phi(x)| \leq c_\phi |Q(x)| / (1 + |x|).$$

Moreover, if $1 \leq p < \infty$, $w \in A_p$ and $u = |Q|^p w$, then $\phi - \mathcal{P}_\phi$ belongs to $L_u^{p'/(p-1)}$, the dual space of L_u^p , with norm bounded by a constant depending on w times c_ϕ . (When $p = 1$, we interpret this to mean that $(\phi - \mathcal{P}_\phi)/Qw$ is bounded by a multiple of c_ϕ .)

PROOF. We have $\phi(x) - \mathcal{P}_\phi(x) = Q(x)\psi(x)$, where

$$(3.2) \quad \psi(x) = \mathcal{D}_y \left(\frac{\phi(x) - \phi(y)}{x - y} \right).$$

As noted in Lemma (2.2)(ii) and its proof, $\psi \in C^\infty$ and

$$\frac{\phi(x) - \phi(y)}{x - y} = \int_0^1 \phi'(sx + (1-s)y) ds.$$

Applying $\mathcal{D}_y$ to both sides and recalling that $\mathcal{D}_y$ has order $N-1$, we see $|\psi(x)| \leq c_\phi$. Moreover, for large $|x|$, formula (3.2) gives $|\psi(x)| \leq c_\phi |x|^{-1}$. Combining estimates, we obtain the first statement of the lemma.

For the second statement, as noted in the introduction,

$$\int_{\mathbf{R}} \frac{w(x)^{-1/(p-1)}}{(1+|x|)^{p'}} dx = c^{p'} < \infty$$

if $w \in A_p$, $1 < p < \infty$. The analogue for $p=1$ is $w(x)^{-1}/(1+|x|) \leq c < \infty$. These easily imply that $|Q(x)|/(1+|x|) \in L_{u^{-1/(p-1)}}^{p'}$ with norm bounded by c , and the second statement follows from the first.

LEMMA (3.3). *Let z and a_{k_0} satisfy $|z - a_{k_0}| = \min_k |z - a_k|$. Then*

$$(i) \quad \sup_{t>0} \left| \phi_t(x-z) - \mathcal{P}_{\phi_t(x-\cdot)}(z) \right| \leq c \frac{|Q(z)|}{|Q(x)|} \frac{1}{|x - a_{k_0}|},$$

if $|z - a_{k_0}| < \frac{1}{2}|x - a_{k_0}|$;

$$(ii) \quad \sup_{t>0} \left| \mathcal{P}_{\phi_t(x-\cdot)}(z) \right| \leq c \frac{|Q(z)|}{|Q(x)|} \frac{1}{|z - a_{k_0}|},$$

if $|z - a_{k_0}| > \frac{1}{2}|x - a_{k_0}|$;

$$(iii) \quad |Q(x)| \leq c |Q(z)|,$$

if $|z - a_{k_0}| > \frac{1}{2}|x - a_{k_0}|$.

In all cases, the constant c is independent of x and z ; in fact, in (iii), c depends only on the degree of Q , and in (i) and (ii) it depends only on Q and the bounds on $(1+|x|)^{\alpha+1} |\phi^{(\alpha)}(x)|$, $\alpha = 0, \dots, N$.

PROOF. For (iii), note $|x - z| \leq |x - a_{k_0}| + |a_{k_0} - z| \leq 3|z - a_{k_0}| \leq 3|z - a_k|$ for any k . Hence, $|x - a_k| \leq |x - z| + |z - a_k| \leq 4|z - a_k|$. Thus, each factor of $|Q(x)|$ is bounded by 4 times the corresponding factor of $|Q(z)|$.

It is enough to prove (i) and (ii) in case $a_{k_0} = 0$; that this is so follows by denoting $(\tau_a \phi)(x) = \phi(x - a)$ and observing that

$$(3.4) \quad \mathcal{P}_{\tau_a \phi}^{\tau_a Q}(z) = (\tau_a \mathcal{P}_\phi^Q)(z).$$

Choose α_0 so that $|\phi^{(\alpha)}(x)| \leq c_0(1+|x|)^{-\alpha-1}$ for $\alpha = 0, \dots, N$. Then $|\phi_t^{(\alpha)}(x)| = t^{-\alpha-1} |\phi^{(\alpha)}(x/t)| \leq c_0(t+|x|)^{-\alpha-1} \leq c_0|x|^{-\alpha-1}$ for such α . We will first prove (ii) for x in a bounded set, say $|x| \leq A = 10\{\max_k |a_k| + 1\}$. From the definition of $\mathcal{D}$,

$$\begin{aligned} \left| \mathcal{D}_y \left(\frac{\phi_t(x-y)}{z-y} \right) \right| &\leq c \max_k \max_{0 \leq i+j < \mu_k} \frac{|\phi_t^{(j)}(x-a_k)|}{|z-a_k|^{j+1}} \\ &\leq cc_0 \max_k \max_{0 \leq i+j < \mu_k} \frac{1}{|z-a_k|^{i+1} |x-a_k|^{j+1}}. \end{aligned}$$

Since $a_{k_0} = 0$ is the closest a_k to z , $|z - a_k| \geq |z|$ for all k . For the same reason, there is a constant $c > 0$ depending on Q so that if $k \neq k_0$, $|z - a_k| \geq c > 0$. Moreover, if $k = k_0$, $|z - a_{k_0}| = |z| > |x|/2$ by hypothesis. Hence, the last expression is at most

$$\frac{cc_0}{|z|} \left\{ \max_{k \neq k_0} \max_{0 \leq j < \mu_k} \frac{1}{|x - a_k|^{j+1}} + \max_{0 \leq i+j < \mu_{k_0}} \frac{1}{|x|^{i+j+1}} \right\}.$$

Since $|x| \leq A$, this is bounded by

$$\frac{cc_0}{|z|} \max_k \frac{1}{|x - a_k|^{\mu_k}} \leq \frac{cc_0}{|z|} \frac{1}{|Q(x)|}.$$

Using the definition of $\mathcal{P}$, we then obtain (ii) for $|x| \leq A$.

To prove (ii) for large $|x|$, i.e., $|x| > A$, we apply formula (2.10) to the function $\phi_t(x - \cdot)$, x fixed, to obtain

$$(3.5) \quad \mathcal{P}_{\phi_t(x-\cdot)}(z) = \sum_{j=0}^{N-1} \frac{(-1)^j}{j!} \phi_t^{(j)}(x) z^j + Q(z) \sum_{k=1}^n \sum_{l=1}^{\mu_k} \frac{A_{k,l}}{(z - a_k)^l} \\ \cdot \sum_{j=0}^{l-1} \frac{(-1)^j}{j!} \left\{ \phi_t^{(j)}(x - a_k) - \sum_{i=0}^{N-j-1} \frac{(-1)^i}{i!} \phi_t^{(j+i)}(x) a_k^i \right\} (z - a_k)^j.$$

Now $|z|$ is also large since $|z| > |x|/2$. The first sum on the right of (3.5) is bounded in absolute value by $\sum_{j=0}^{N-1} c_0 |x|^{-j-1} |z|^j$. However,

$$|x|^{-j-1} |z|^j = \left(\frac{|z|}{|x|} \right)^{j+1} \frac{1}{|z|} \leq c \left(\frac{|z|}{|x|} \right)^N \frac{1}{|z|}$$

since $j+1 \leq N$ and $|z| > |x|/2$. Since $|x|$ is large, $|Q(x)| \sim |x|^N$, that is, $|Q(x)|$ is bounded above and below by positive multiples of $|x|^N$. Also $|z|^N \sim |Q(z)|$, and therefore the first sum on the right of (3.5) is bounded by $cc_0 |Q(z)|/|Q(x)||z|$, as desired.

Consider the second term on the right in (3.5). Since $|x|$ is large, Taylor's theorem shows that each term in curly brackets is bounded by a multiple of $|\phi_t^{(N)}|$ evaluated at a point whose absolute value is comparable to $|x|$. Thus, each term in curly brackets is bounded by $cc_0 |x|^{-N-1}$, and so by $cc_0 |x|^{-N}$. Also, since $|z|$ is large and $j \leq l-1$, $|z - a_k|^{-l+j} \leq c |z|^{-l+j} \leq c |z|^{-1}$. Combining these facts, we see that for $|x| > A$ and $|z| > |x|/2$ the second term on the right of (3.5) is bounded in absolute value by

$$|Q(z)| |z|^{-1} cc_0 |x|^{-N} \leq cc_0 |Q(z)|/|Q(x)||z|.$$

This completes the proof of (ii).

To prove (i) for $|x| < A$, write

$$\phi_t(x - z) - \mathcal{P}_{\phi_t(x-\cdot)}(z) = Q(z) \mathcal{O}_y \left(\frac{\phi_t(x - z) - \phi_t(x - y)}{z - y} \right).$$

Split $\mathfrak{D}_y = \mathfrak{D}_y^0 + \mathfrak{D}_y^1$ where $\mathfrak{D}_y^0$ is supported at $a_{k_0} = 0$ and $\mathfrak{D}_y^1$ at $\{a_k\} \setminus \{0\}$. Since

$$\frac{\phi_t(x-z) - \phi_t(x-y)}{z-y} = -\int_0^1 \phi_t'(x-y-s(z-y)) ds,$$

we have

$$\begin{aligned} \left| \mathfrak{D}_y^0 \left(\frac{\phi_t(x-z) - \phi_t(x-y)}{z-y} \right) \right| &\leq c \max_{0 \leq \alpha < \mu_{k_0}} \int_0^1 |\phi_t^{(\alpha+1)}(x-sz)| ds \\ (3.6) \qquad &\leq c \max_{\substack{0 \leq \alpha < \mu_{k_0} \\ |u| \leq |z|}} |\phi_t^{(\alpha+1)}(x-u)|. \end{aligned}$$

By assumption, $|u| \leq |z| < |x|/2$, and formula (3.6) is therefore bounded by $cc_0 \max_{0 \leq \alpha < \mu_{k_0}} |x|^{-\alpha-2}$. For $|x| < A$, this is at most

$$cc_0 |x|^{-\mu_{k_0}-1} \leq cc_0 |x|^{-1} |Q(x)|^{-1},$$

as desired. Also,

$$\left| \mathfrak{D}_y^1 \left(\frac{\phi_t(x-z) - \phi_t(x-y)}{z-y} \right) \right| \leq c \left\{ |\phi_t(x-z)| + \max_{\substack{k \\ 0 \leq \alpha < \mu_k}} |\phi_t^{(\alpha)}(x-a_k)| \right\}$$

since $|z-a_k| \geq c > 0$ for $k \neq k_0$. This is at most

$$cc_0 \left\{ |x-z|^{-1} + \max_{k; 0 \leq \alpha < \mu_k} |x-a_k|^{-\alpha-1} \right\}.$$

We have $|x-z| \geq |x| - |z| > |x|/2$. Hence, since x is bounded, the last estimate is at most $cc_0 \max_k |x-a_k|^{-\mu_k}$, so that

$$(3.7) \qquad \left| \mathfrak{D}_y^1 \left(\frac{\phi_t(x-z) - \phi_t(x-y)}{z-y} \right) \right| \leq cc_0 \frac{1}{|Q(x)|}, \quad |x| < A.$$

This is bounded by $cc_0 |Q(x)|^{-1} |x|^{-1}$ since $|x| < A$, and (i) follows for $|x| < A$.

To prove (i) for $|x| > A$, we use (3.5). Recall that each term there in curly brackets is bounded by $c |\phi_t^{(N)}(\xi)|$ with $|\xi| \sim |x|$, and so is bounded by $cc_0 |x|^{-N-1}$. Furthermore, note that the term in curly brackets corresponding to $k = k_0$ is zero. For $k \neq k_0$, $|z-a_k| \geq c > 0$ and therefore $|z-a_k|^{-l+j}$ is bounded since $j \leq l-1$. Hence, for $|x| > A$, the second term on the right of (3.5) is majorized in absolute value by $cc_0 |Q(z)| |x|^{-N-1} \leq cc_0 |Q(z)|/|Q(x)| |x|$.

To complete the proof of (i) for $|x| > A$, it is then enough by (3.5) to estimate the difference between $\phi_t(x-z)$ and the first term on the right of (3.5). Taylor's theorem shows this difference is in absolute value at most $|z|^N |\phi_t^{(N)}(\xi)|$ for some ξ between x and $x-z$. This is bounded by $cc_0 |z|^N |x|^{-N-1}$ since $|z| < |x|/2$. We have $|x|^{-N} \sim |Q(x)|^{-1}$ since $|x|$ is large. Finally, $|z|^N \leq c |Q(z)|$ since if $|z|$ is large, $|z|^N \sim |Q(z)|$, while if $|z|$ is bounded, $|z|^N \leq c |z|^{\mu_{k_0}} \leq c |Q(z)|$ since the other factors of $|Q(z)|$ are all bounded below by positive constants. This completes the proof of the lemma.

As a corollary, we obtain the following estimates.

LEMMA (3.8). If z and a_{k_0} satisfy $|z - a_{k_0}| = \min_k |z - a_k|$, then

$$(i) \quad \sup_{(\xi, t) \in \mathbb{R}_+^2} \left(\frac{t}{t + |\xi - x|} \right)^{N+1} |\phi_t(\xi - z) - \mathcal{P}_{\phi, (\xi - \cdot)}(z)| \leq c \frac{|Q(z)|}{|Q(x)|} \frac{1}{|x - a_{k_0}|}$$

if $|z - a_{k_0}| < \frac{1}{2} |x - a_{k_0}|$;

$$(ii) \quad \sup_{(\xi, t) \in \mathbb{R}_+^2} \left(\frac{t}{t + |\xi - x|} \right)^{N+1} |\mathcal{P}_{\phi, (\xi - \cdot)}(z)| \leq c \frac{|Q(z)|}{|Q(x)|} \frac{1}{|z - a_{k_0}|}$$

if $|z - a_{k_0}| > \frac{1}{2} |x - a_{k_0}|$. The constant c depends only on Q and the bounds on $(1 + |x|)^{\alpha+1} |\phi^{(\alpha)}(x)|$, $\alpha = 0, \dots, N$.

PROOF. Given ϕ , let $\psi(u) = \phi(u + (\xi - x)/t)$. Note that

$$(1 + |u|)^{\alpha+1} |\psi^{(\alpha)}(u)| = (1 + |u|)^{\alpha+1} |\phi^{(\alpha)}(u + (\xi - x)/t)|,$$

so that the sup over u of the expression on the left is at most $(1 + |\xi - x|/t)^{\alpha+1}$ times a multiple of the sup over u of $(1 + |u|)^{\alpha+1} |\phi^{(\alpha)}(u)|$. Since $\psi_t(x - z) = \phi_t(\xi - z)$, it then follows by applying Lemma (3.3)(i) to ψ that if $|z - a_{k_0}| = \min_k |z - a_k| < \frac{1}{2} |x - a_{k_0}|$,

$$|\phi_t(\xi - z) - \mathcal{P}_{\phi, (\xi - \cdot)}(z)| \leq c \left(1 + \frac{|\xi - x|}{t} \right)^{N+1} \frac{|Q(z)|}{|Q(x)|} \frac{1}{|x - a_{k_0}|}.$$

Here c depends only on Q and the bounds on $(1 + |u|)^{\alpha+1} |\phi^{(\alpha)}(u)|$, $\alpha = 0, \dots, N$. This proves part (i) of the lemma. Part (ii) follows in the same way from Lemma (3.3)(ii).

4. Proof of Theorem 1. Let $1 < p < \infty$, $w \in A_p$, Q be a polynomial of degree N with all real zeros and $u = |Q|^p w$. Let

$$f(x, t) = \int_{\mathbb{R}} f(z) \left[\phi_t(x - z) - \mathcal{P}_{\phi, (x - \cdot)}^Q(z) \right] dz$$

and

$$N_\lambda f(x) = \sup_{(\xi, t) \in \mathbb{R}_+^2} \left(\frac{t}{t + |\xi - x|} \right)^\lambda |f(\xi, t)|.$$

Note that if $f \in L_u^p$, then by Lemma (3.1), the integral defining $f(x, t)$ converges absolutely.

For each zero a_{k_0} of Q , define

$$f_{k_0}(z) = \begin{cases} f(z) & \text{if } |z - a_{k_0}| = \min_k |z - a_k|, \\ 0 & \text{otherwise.} \end{cases}$$

By summation, it is enough to prove the theorem for $f = f_{k_0}$. Thus, the estimates of Lemma (3.3) are valid for any z where $f(z) \neq 0$. We may also assume for simplicity that $a_{k_0} = 0$; that we may do so follows by translating variables, using the identity (3.4), and observing that the condition $w(x) \in A_p$ is independent of a translation of x .

We have

$$|f(\xi, t)| \leq \int_{|z| < |x|/2} |f(z)| |\phi_t(\xi - z) - \mathcal{P}_{\phi_t(\xi - \cdot)}(z)| dz \\ + \int_{|z| > |x|/2} |f(z)| |\phi_t(\xi - z)| dz + \int_{|z| > |x|/2} |f(z)| |\mathcal{P}_{\phi_t(\xi - \cdot)}(z)| dz.$$

Multiply both sides of this inequality by $t^\lambda / (t + |x - \xi|)^\lambda$, and let $A(x)$, $B(x)$ and $C(x)$ denote the suprema over $(\xi, t) \in \mathbf{R}_+^2$ of the resulting three terms on the right, resp. Thus, $N_\lambda f(x) \leq A(x) + B(x) + C(x)$, and it is enough to estimate the norms of A , B and C .

By Lemma (3.8)(i), if $\lambda \geq N + 1$,

$$A(x) \leq c \frac{1}{|Q(x)| |x|} \int_{|z| < |x|/2} |f(z)| |Q(z)| dz.$$

Therefore,

$$\|A\|_{p,u} \leq c \left\| \int_{|z| < |x|} |f(z)| |Q(z)| dz \right\|_{p, w(x)|x|^{-p}}.$$

Applying Hardy's inequality in the form

$$\left\| \int_{|z| < |x|} g(z) dz \right\|_{p, w(x)|x|^{-p}} \leq c \|g\|_{p,w}, \quad w \in A_p$$

(see, e.g., [5]), we obtain $\|A\|_{p,u} \leq c \|fQ\|_{p,w} = c \|f\|_{p,u}$ as desired.

By Lemma (3.8)(ii), if $\lambda \geq N + 1$,

$$C(x) \leq c \frac{1}{|Q(x)|} \int_{|z| > |x|/2} |f(z)| |Q(z)| \frac{1}{|z|} dz,$$

$$\|C\|_{p,u} \leq c \left\| \int_{|z| > |x|/2} |f(z)| |Q(z)| \frac{1}{|z|} dz \right\|_{p,w}.$$

Applying the dual version of Hardy's inequality, that is,

$$\left\| \int_{|z| > |x|/2} g(z) dz \right\|_{p,w} \leq c \|g\|_{p, w(x)|x|^p}, \quad w \in A_p$$

(see, e.g., [5]), we get the desired estimate

$$\|C\|_{p,u} \leq c \|f(x)Q(x)/x\|_{p, w(x)|x|^p} = c \|f\|_{p,u}.$$

By Lemma (3.3)(iii),

$$B(x) \leq \frac{c}{|Q(x)|} \sup_{(\xi, t) \in \mathbf{R}_+^2} \left(\frac{t}{t + |\xi - x|} \right)^\lambda \int_{|z| > |x|/2} |f(z)Q(z)| |\phi_t(\xi - z)| dz.$$

Enlarging the domain of integration on the right to all of $\mathbf{R}$, it follows that the sup on the right is at most the usual tempered tangential maximal function of order λ of $|fQ|$ formed with $|\phi_t|$ as the approximation of the identity. As noted in the introduction, this maximal function is bounded on L_w^p if $\lambda > 1$ and $w \in A_p$. Hence, $\|B\|_{p,u} \leq c \|fQ\|_{p,w} = c \|f\|_{p,u}$. This completes the proof of the theorem.

Theorem 1 has a weak-type analogue when $p = 1$. To state it, we will use the notation $m_w(E) = \int_E w(x) dx$ for the w -measure of a set E .

THEOREM (4.1). *Let $Q(x)$, $f(x, t)$ and $N_\lambda f(x)$ be as in Theorem 1, and let $w \in A_1$. If $\lambda \geq N + 1$ and $\lambda > 1$, then*

$$m_w\{x: N_\lambda f(x)|Q(x)| > s\} \leq cs^{-1}\|f\|_{1,|Q|w}, \quad s > 0,$$

where c is independent of f and s .

PROOF. As in the proof of Theorem 1, it is enough to show that $A(x)$, $B(x)$ and $C(x)$ satisfy the estimate. For A , we have

$$A(x) \leq c \frac{1}{|Q(x)||x|} \int_{|z| < |x|/2} |f(z)||Q(z)| dz,$$

so that

$$A(x)|Q(x)| \leq c \frac{1}{|x|} \int_{|x-z| < 2|x|} |f(z)Q(z)| dz \leq c(fQ)^*(x),$$

where “*” denotes the Hardy-Littlewood maximal function. Hence,

$$m_w\{x: A(x)|Q(x)| > s\} \leq m_w\{x: (fQ)^*(x) > s/c\} \leq \frac{c}{s} \int_{\mathbf{R}} |fQ|w dx,$$

by [6], since $w \in A_1$. We also have

$$C(x) \leq \frac{c}{|Q(x)|} \int_{|z| > |x|/2} |f(z)||Q(z)| \frac{1}{|z|} dz.$$

Thus,

$$\begin{aligned} m_w\{x: C(x)|Q(x)| > s\} &\leq \frac{1}{s} \int_{\mathbf{R}} C(x)|Q(x)|w(x) dx \\ &\leq \frac{c}{s} \int_{\mathbf{R}} |f(z)||Q(z)| \left\{ \frac{1}{|z|} \int_{|x| < 2|z|} w(x) dx \right\} dz. \end{aligned}$$

Now using the estimate

$$\frac{1}{|z|} \int_{|x| < 2|z|} w(x) dx \leq \frac{1}{|z|} \int_{|x-z| < 3|z|} w(x) dx \leq cw^*(z) \leq cw(z),$$

since $w \in A_1$, we see the last expression is at most $cs^{-1}\|f\|_{1,|Q|w}$ as desired. Finally, recall that $B(x)|Q(x)|$ is majorized by a multiple of the usual tempered tangential maximal function of order λ of $|fQ|$ at x , formed with $|\phi_t|$ as approximation of the identity. Denoting this by $N'_\lambda(fQ)(x)$ and using the known fact (see [9]) that if $\lambda > 1$ and $w \in A_1$, then $m_w\{x: N'_\lambda(g)(x) > s\} \leq (c/s)\|g\|_{1,w}$, we immediately obtain the desired estimate for B . This completes the proof.

5. Theorem 2. In this section, we prove Theorem 2 and deduce several corollaries. As usual, we let $u = |Q|^p w$ where $1 < p < \infty$, Q has only real zeros and $w \in A_p$.

We will first show if $f \in L_u^p$ and l_f is defined by

$$\langle l_f, \phi \rangle = \int_{\mathbf{R}} f(z) [\phi(z) - \mathcal{P}_\phi(z)] dz, \quad \phi \in \mathcal{S},$$

$\mathcal{P}_\phi = \mathcal{P}_\phi^Q$, then l_f is a tempered distribution in H_u^p and

$$(5.1) \quad \|l_f\|_{H_u^p} \leq c \|f\|_{L_u^p}$$

with c independent of f . In fact, by the second statement in Lemma (3.1), it follows immediately that l_f defines a tempered distribution. Moreover, since the H_u^p norm of l_f is equivalent to the L_u^p norm of the nontangential maximal function of

$$\langle l_f, \phi_t(x - \cdot) \rangle = \int_{\mathbf{R}} f(z) \left[\phi_t(x - z) - \mathcal{P}_{\phi_t(x - \cdot)}(z) \right] dz,$$

we obtain (5.1) from Theorem 1.

Now let l be any distribution in H_u^p , and let $l(z, s) = \langle l, \psi_s(z - \cdot) \rangle = (l * \psi_s)(z)$ for a fixed $\psi \in \mathcal{S}$ with $\int_{\mathbf{R}} \psi(z) dz = 1$. By hypothesis, the L_u^p norm of $l(z, s)$ as a function of z is bounded in s by $\|l\|_{H_u^p}$. Hence, since $p > 1$, there exist $s_m \rightarrow 0$ and $f \in L_u^p$ so that $l(z, s_m)$ converges weakly in L_u^p to f and $\|f\|_{L_u^p} \leq \|l\|_{H_u^p}$. Our goal is to show that $l = l_f$.

By Lemma (3.1), $\phi - \mathcal{P}_\phi$ belongs to the dual of L_u^p , so by weak convergence,

$$(5.2) \quad \int_{\mathbf{R}} l(z, s_m) [\phi(z) - \mathcal{P}_\phi(z)] dz \rightarrow \langle l_f, \phi \rangle$$

as $m \rightarrow \infty$. Let us denote

$$\langle l(s), \phi \rangle = \int_{\mathbf{R}} l(z, s) [\phi(z) - \mathcal{P}_\phi(z)] dz,$$

$$\langle \tilde{l}(s), \phi \rangle = \langle l * \psi_s, \phi \rangle = \int_{\mathbf{R}} l(z, s) \phi(z) dz.$$

Since $l(z, s) \in L_u^p$, $l(s)$ defines a distribution in H_u^p by what has already been proved. As we will now show, the same is true for $\tilde{l}(s)$. That $\tilde{l}(s)$ defines a distribution follows from the fact that, for $s > 0$, $l(z, s)$ is a locally bounded function of z which is also in L_u^p : thus, $l(z, s) \in L_{(1+|x|)^{Np/w}}^p$, while any $\phi \in \mathcal{S}$ belongs to the dual space $L_{(1+|x|)^{-Np'/w'-1/(p-1)}}^{p'}$ (see the end of the introduction). To see that $\tilde{l}(s) \in H_u^p$, we will show that its radial maximal function

$$M_0(x) = \sup_{t>0} |\langle \tilde{l}(s), \phi_t(x - \cdot) \rangle|, \quad \phi \in \mathcal{S},$$

is pointwise less than a constant times the sum of the tangential maximal functions of l formed from ϕ and from ψ . In fact,

$$\langle \tilde{l}(s), \phi_t(x - \cdot) \rangle = (l * \psi_s * \phi_t)(x) = \int_{\mathbf{R}} l(z, s) \phi_t(x - z) dz,$$

so that given $M > 0$, there is a constant c with

$$\begin{aligned} |\langle \tilde{l}(s), \phi_t(x - \cdot) \rangle| &\leq c \frac{1}{t} \int_{\mathbf{R}} |l(z, s)| \left(1 + \frac{|x - z|}{t} \right)^{-M} dz \\ &\leq c \left[\sup_{(z, s)} \left(1 + \frac{|x - z|}{s} \right)^{-\lambda} |l(z, s)| \right] \\ &\quad \cdot \frac{1}{t} \int_{\mathbf{R}} \left(1 + \frac{|x - z|}{s} \right)^{\lambda} \left(1 + \frac{|x - z|}{t} \right)^{-M} dz. \end{aligned}$$

If $t \leq s$ and $\lambda > 0$,

$$\frac{1}{t} \int_{\mathbf{R}} \left(1 + \frac{|x-z|}{s}\right)^{\lambda} \left(1 + \frac{|x-z|}{t}\right)^{-M} dz \leq \frac{1}{t} \int_{\mathbf{R}} \left(1 + \frac{|x-z|}{t}\right)^{\lambda-M} dz,$$

which is a constant independent of x and t if $M > \lambda + 1$. This shows that if $M > \lambda + 1$, $\lambda > 0$, then

$$\sup_{t \leq s} |\langle \tilde{l}(s), \phi_t(x - \cdot) \rangle| \leq c \sup_{(z, s)} \left(1 + \frac{|x-z|}{s}\right)^{-\lambda} |l(z, s)|.$$

The expression on the right is the tangential maximal function of l formed from ψ . To obtain an estimate for $t > s$, we only need to note that $l * \psi_s * \phi_t = (l * \phi_t) * \psi_s$ and repeat the argument above, obtaining for $M > \lambda + 1$, $\lambda > 0$,

$$\sup_{t > s} |\langle \tilde{l}(s), \phi_t(x - \cdot) \rangle| \leq c \sup_{(z, t)} \left(1 + \frac{|x-z|}{t}\right)^{-\lambda} |(l * \phi_t)(z)|.$$

Combining inequalities proves the desired estimate for $M_0(x)$.

Next, we will show that $\tilde{l}(s) = l(s)$. This will prove that $l = l_f$ since the fact that $\int \psi = 1$ implies $\langle \tilde{l}(s), \phi \rangle \rightarrow \langle l, \phi \rangle$ as $s \rightarrow 0$, while by (5.2), $\langle l(s_m), \phi \rangle \rightarrow \langle l_f, \phi \rangle$. Let $l_1(s) = \tilde{l}(s) - l(s)$, so that $l_1 \in H_u^p$ and

$$(5.3) \quad \langle l_1(s), \phi \rangle = \int_{\mathbf{R}} l(z, s) \mathcal{P}_{\phi}(z) dz.$$

We want to show that $l_1(s) \equiv 0$. Write

$$\mathcal{P}_{\phi}(z) = Q(z) \mathcal{Q}_y[\phi(y)/(z-y)] = \sum_{k=1}^n \sum_{l=1}^{\mu_k} B_{k,l}(z) \delta_{a_k}^{(l-1)} \phi,$$

where the $B_{k,l}(z)$ are polynomials of degree at most $N-1$. Since any such polynomial is in $L_{(1+|x|)^{-Np'}}^{p'}$, we may integrate term-by-term to get

$$l_1(s) = \sum_{k=1}^n \sum_{l=1}^{\mu_k} B_{k,l} \delta_{a_k}^{(l-1)}, \quad \text{where } B_{k,l} = \int_{\mathbf{R}} l(z, s) B_{k,l}(z) dz.$$

In particular, l_1 has compact support and also, by Lemma (2.4), $\langle l_1(s), \phi - \mathcal{P}_{\phi} \rangle = 0$. Therefore, $\langle l_1(s), \phi \rangle = \langle l_1(s), \phi - \mathcal{P}_{\phi} \rangle + \langle l_1(s), \mathcal{P}_{\phi} \rangle = 0 + \langle l_1(s), \mathcal{P}_{\phi} \rangle$, and we immediately obtain $l_1(s) = 0$ by applying the following lemma.

LEMMA (5.4). *Let $1 < p < \infty$ and $u(x) = |Q(x)|^p w(x)$ where Q is a polynomial of degree N with all real zeros and $w \in A_p$. If l_1 is a distribution with compact support such that $l_1 \in H_u^p$, then $\langle l_1, x^k \rangle = 0$ for $0 \leq k \leq N-1$.*

PROOF. Assume conversely that $\langle l_1, x^k \rangle = c_k \neq 0$ for some $0 \leq k \leq N-1$. Let $\rho(x) \in C^\infty$ with $\rho(x) = 1$ for $|x| < 1$, $\rho(x) = 0$ for $|x| > 2$ and $0 \leq \rho(x) \leq 1$. Set $\phi(x) = x^k \rho(x)$. Then $\phi_t(x) = t^{-1} \phi(x/t) = t^{-k-1} x^k \rho(x/t)$, and for t large we have

$$\begin{aligned} \langle l_1, \phi_t \rangle &= t^{-k-1} \langle l_1, x^k \rho(x/t) \rangle = t^{-k-1} [\langle l_1, x^k \rangle - \langle l_1, x^k (1 - \rho(x/t)) \rangle] \\ &= t^{-k-1} c_k, \end{aligned}$$

using the fact that $x^k(1 - \rho(x/t)) = 0$ on the support of l_1 when t is large. Setting $\psi(x) = \phi(-x)$, we see that the function $l_1(z, t) = \langle l_1, \psi_t(z - \cdot) \rangle$ satisfies $l_1(0, t) = t^{-k-1}c_k$ for large t . Thus,

$$\sup_{\Gamma_\gamma(x)} |l_1(z, t)| \geq |c_k| \left(\frac{|x|}{\gamma} \right)^{-k-1} \quad \text{for } |x| \text{ large.}$$

This, however, contradicts the fact that $l_1 \in H_u^p$ since for large $|x|$ and $k \leq N-1$, $(|x|^{-k-1})^p u(x) \geq c|x|^{(N-k-1)p} w(x) \geq cw(x)$, and $w(x)$ is not integrable at infinity. This completes the proof of the lemma.

The only part of Theorem 2 which remains to be proved concerns the uniqueness of the correspondence between l and f . However, if $g \in L_u^p$ and

$$\int_{\mathbf{R}} f(z) [\phi(z) - \mathfrak{P}_\phi(z)] dz = \int_{\mathbf{R}} g(z) [\phi(z) - \mathfrak{P}_\phi(z)] dz,$$

for $\phi \in \mathfrak{S}$, then for any ϕ which is zero in a small neighborhood of each a_k , $\int_{\mathbf{R}} f(z)\phi(z) dz = \int_{\mathbf{R}} g(z)\phi(z) dz$. Since f and g are locally integrable away from the a_k 's, it follows that $f = g$ a.e. This completes the proof of the theorem.

COROLLARY (5.5). *Let $1 < p < \infty$ and $u = |Q|^p w$ where Q has all real zeros and $w \in A_p$. If $l \in H_u^p$ and $l(x, s) = (l * \psi_s)(x)$, $s > 0$, $\psi \in \mathfrak{S}$, then*

$$\int_{\mathbf{R}} l(x, s) x^j dx = 0, \quad j = 0, \dots, N-1.$$

PROOF. As shown in the proof of Theorem 2 (see (5.3)) and use the fact that $l_1(s) = 0$,

$$\int_{\mathbf{R}} l(x, s) \mathfrak{P}_\phi(x) dx = 0.$$

Picking $\phi(x) = x^j \rho(x)$, where $j = 0, \dots, N-1$ and ρ is a function in $\mathfrak{S}$ which equals 1 on the support of $\mathfrak{D}$, we have $\mathfrak{P}_\phi(x) = \mathfrak{P}_{x^j}(x) = x^j$, and the corollary follows.

We remark that Corollary (5.5) can also be derived from Theorem 2 by applying Fubini's theorem and Lemma (2.6).

COROLLARY (5.6). *Let $1 < p < \infty$, Q be a polynomial with all real zeros and $w \in A_p$. If $f \in L_{|Q|^p w}^p$, $\phi \in \mathfrak{S}$ and $\int \phi = 1$, then*

$$\left\| \sup_{\Gamma_\gamma(x)} \left| \int_{\mathbf{R}} f(z) [\phi_t(y-z) - \mathfrak{P}_{\phi_t(y-\cdot)}^Q(z)] dz \right| \right\|_{L_{|Q|^p w}^p}$$

and

$$\left\| \sup_{\Gamma_\gamma(x)} \left| \int_{\mathbf{R}} f(z) Q(z) \phi_t(y-z) dz \right| \right\|_{L_w^p}$$

are equivalent.

PROOF. We have $f \in L_{|Q|^p w}^p$ if and only if $fQ \in L_w^p$. Moreover, $\|f\|_{p, |Q|^p w} = \|fQ\|_{p, w}$. The corollary then follows immediately from Theorem 2 and the fact that $\|fQ\|_{p, w}$ is equivalent to the second norm in the statement.

6. Convergence of $f(x, t)$. In this section, we give a proof based on the estimates in §3 of the pointwise convergence a.e. of $f(x, t)$ as $t \rightarrow 0$. We also study norm convergence.

THEOREM (6.1). *Let $1 \leq p < \infty$ and $u = |Q|^p w$ where Q is a polynomial of degree N with all real zeros and $w \in A_p$. Let ϕ satisfy*

$$(6.2) \quad n_\phi = \max_{|\alpha| \leq N} \|(1 + |z|)^{\alpha+1+\varepsilon} \phi^{(\alpha)}(z)\|_\infty < \infty$$

for some $\varepsilon > 0$. If $f \in L_u^p$ and

$$f(x, t) = \int_{\mathbf{R}} f(z) \left[\phi_t(x - z) - \mathcal{P}_{\phi_t(x-\cdot)}^Q(z) \right] dz,$$

then

$$\lim_{\substack{t \rightarrow 0 \\ |x - x_0| < \gamma t}} f(x, t) = \left(\int_{\mathbf{R}} \phi dz \right) f(x_0)$$

at any Lebesgue point x_0 of f where $Q(x_0) \neq 0$.

PROOF. The proof is a modified version of the usual Lebesgue point proof of the convergence of approximations of the identity. As usual, we may assume that $x_0 = 0$ and $\int \phi = 1$.

First, consider the case when ϕ is bounded and has compact support. Then if t is small enough and $|x| < \gamma t$, $\phi_t(x - \cdot)$ is supported away from the zeros of Q . Thus, $\mathcal{P}_{\phi_t(x-\cdot)}^Q \equiv 0$ and

$$|f(x, t) - f(0)| = \left| \int_{\mathbf{R}} [f(z) - f(0)] \phi_t(x - z) dz \right|.$$

If $|x| < \gamma t$, there exists a constant c so that $|\phi_t(x - z)| \leq ct^{-1} \chi_{(-ct, ct)}(z)$, and therefore

$$|f(x, t) - f(0)| \leq c \frac{1}{t} \int_{|z| < ct} |f(z) - f(0)| dz,$$

which tends to zero with t since $x_0 = 0$ is a Lebesgue point of f . This completes the proof for this case.

For the general case, write $\phi(x) = \rho(rx)\phi(x) + (1 - \rho(rx))\phi(x) = \phi_1 + \phi_2$, where ρ is a smooth truncation defined by $\rho(x) = 1$ if $|x| < 1$, $\rho(x) = 0$ if $|x| > 2$, and $\rho \in C^\infty$. For fixed r , ϕ_1 has compact support and the corresponding extension $f_1(x, t)$ converges to $(\int \phi_1 dx)f(0)$ as shown above. Furthermore, as $r \rightarrow 0$, $\int \phi_1 dx \rightarrow \int \phi dx$ and the constant n_{ϕ_2} defined by (6.2) with $\phi = \phi_2$ tends to zero. Hence, to prove the theorem, it is enough to show there is a constant A depending on f and $x_0 (= 0)$ such that

$$\sup_{|x| < \gamma t; t < 1} |f(x, t)| \leq A n_\phi.$$

Since $n_{\phi(\cdot + \alpha)} \leq cn_\phi$ if $|\alpha| < \gamma$, it is enough to show that $\sup_{t < 1} |f(0, t)| \leq A n_\phi$.

Combining the estimates in Lemma (3.3), we get

$$|\phi_t(-z) - \mathcal{P}_{\phi_t(-\cdot)}(z)| \leq c_0 |Q(z)| \left[\frac{n_\phi}{1 + |z|} + |\phi_t(-z)| \right],$$

where c_0 depends on Q and x_0 . We also have

$$|\phi_t(-z)| \leq n_\phi t^{-1} (1 + |z|/t)^{-1-\epsilon}.$$

Therefore,

$$\frac{|f(0, t)|}{n_\phi} \leq c_0 \int_{\mathbf{R}} |fQ| (1 + |z|)^{-1} dz + c_0 \int_{\mathbf{R}} |fQ| t^{-1} \left(1 + \frac{|z|}{t} \right)^{-1-\epsilon} dz.$$

By Hölder's inequality, the first integral on the right is at most

$$\|f\|_{p,u} \|w(z)^{-1/p} (1 + |z|)^{-1}\|_{p'} \leq A.$$

Since $t^{-1}(1 + |z|/t)^{-1-\epsilon} \leq c_\delta (1 + |z|)^{-1}$ if $|z| > \delta > 0$, the second is at most a multiple of

$$\int_{|z| < \delta} |fQ| t^{-1} \left(1 + \frac{|z|}{t} \right)^{-1-\epsilon} dz + \int_{|z| > \delta} |fQ| (1 + |z|)^{-1} dz.$$

Of these two integrals, the second was shown above to be bounded by A . The first, since $\epsilon > 0$, is by well-known facts about approximations of the identity bounded by a constant times the Hardy-Littlewood maximal function of $fQ\chi_{(|z| < \delta)}$ evaluated at 0. This is bounded by

$$c \sup_{s < \delta} \frac{1}{s} \int_{|z| < s} |fQ| dz \leq c \sup_{s < \delta} \frac{1}{s} \int_{|z| < s} |f| dz \leq A$$

for small δ , and the proof is complete.

THEOREM (6.3). *With the same assumptions and notation as in Theorem (6.1), $f(x, t)$ converges in L_u^p norm to $(\int_{\mathbf{R}} \phi dz)f(x)$ as $t \rightarrow 0$.*

PROOF. For $1 < p < \infty$, $\sup_{t>0} |f(x, t)| \in L_u^p$ by Theorem 1, and the result follows from Theorem (6.1) by the Lebesgue dominated convergence.

For $p = 1$, the proof has two steps, the first being to show that

$$(6.4) \quad \|f(x, t)\|_{1,u} \leq c \|f\|_{1,u}$$

with c independent of f and $t > 0$, $u = |Q|w$, $w \in A_1$. This is based on estimates very much like those in §3. We may assume that $f(z) = 0$ unless $|z - a_{k_0}| = \min_k |z - a_k|$ and that $a_{k_0} = 0$. Split the integral defining $f(x, t)$ into parts with $|z| > |x|/2$ and $|z| < |x|/2$. For the part with $|z| > |x|/2$,

$$\begin{aligned} |\phi_t(x - z) - \mathcal{P}_{\phi_t(x-\cdot)}(z)| &\leq |\phi_t(x - z)| + |\mathcal{P}_{\phi_t(x-\cdot)}(z)| \\ &\leq c \frac{|Q(z)|}{|Q(x)|} \left\{ |\phi_t(x - z)| + \frac{1}{|z|} \right\} \end{aligned}$$

by Lemma (3.3)(ii) and (iii). The corresponding part of $\|f(x, t)\|_{1,u}$ is then at most

$$c \int_{\mathbf{R}} \left[\int_{|z| > |x|/2} |f(z)| |Q(z)| \left(|\phi_t(x-z)| + \frac{1}{|z|} \right) dz \right] w(x) dx.$$

By Fubini's theorem and the fact that $|x-z| < 3|z|$ if $|x| < 2|z|$, this is at most

$$\begin{aligned} c \int_{\mathbf{R}} |f(z)| |Q(z)| \left[\int_{\mathbf{R}} |\phi_t(x-z)| w(x) dx + \frac{1}{|z|} \int_{|x-z| < 3|z|} w(x) dx \right] dz \\ \leq c \int_{\mathbf{R}} |f(z)| |Q(z)| w^*(z) dz. \end{aligned}$$

Since $w \in A_1$, we have $w^*(z) \leq cw(z)$ for a.e. z , and therefore the last integral is at most $\|f\|_{1,u}$.

For the part of $f(x, t)$ with $|z| < |x|/2$, $|x| < A$, we claim

$$|\phi_t(x-z) - \mathcal{P}_{\phi_t(x-\cdot)}(z)| \leq c(|Q(z)|/|Q(x)|)[\psi_t(x-z) + 1],$$

where $\psi(x) = (1 + |x|)^{-1-\varepsilon}$. In fact, combining (3.6) and (3.7) we get the bound

$$c|Q(z)| \left[\max_{0 \leq \alpha < \mu_{k_0}} t^{-\alpha-2} \left(1 + \frac{|x|}{t} \right)^{-\alpha-2-\varepsilon} + \frac{1}{|Q(x)|} \right].$$

However, since $(1 + |x|/t)^{-\alpha-1} \leq (|x|/t)^{-\alpha-1}$,

$$t^{-\alpha-2} \left(1 + |x|/t \right)^{-\alpha-2-\varepsilon} \leq \psi_t(x) |x|^{-\alpha-1} \leq \psi_t(x) |Q(x)|^{-1},$$

since $|Q(x)| \leq c|x|^{\mu_{k_0}} \leq c|x|^{\alpha+1}$ if $\alpha+1 \leq \mu_{k_0}$ and $|x| < A$. The claim above now follows immediately from the fact that $\psi_t(x)$ and $\psi_t(x-z)$ are comparable for $|z| < |x|/2$. The corresponding part of $\|f(x, t)\|_{1,u}$ is then at most

$$\begin{aligned} c \int_{|x| < A} \left[\int_{|z| < |x|/2} |f(z)| |Q(z)| (\psi_t(x-z) + 1) dz \right] w(x) dx \\ \leq c \int_{|z| < A/2} |f(z)| |Q(z)| \left[\int_{\mathbf{R}} \psi_t(x-z) w(x) dx + \int_{|x| < A} w(x) dx \right] dz. \end{aligned}$$

The two inner integrals are bounded by $cw^*(z)$ for $|z| < A/2$, and the entire expression is at most $\|f\|_{1,u}$ since $w \in A_1$.

Finally, for the part of $f(x, t)$ with $|z| < |x|/2$, $|x| > A$, we claim

$$|\phi_t(x-z) - \mathcal{P}_{\phi_t(x-\cdot)}(z)| \leq c(|Q(z)|/|Q(x)|)\psi_t(x-z),$$

where ψ is as above. In fact, as shown in §3, we have the bound $c|Q(z)|/|\phi_t^{(N)}(\xi)|$ where $|\xi| \sim |x|$. Thus

$$\begin{aligned} |\phi_t^{(N)}(\xi)| &\leq ct^{-N-1}(1 + |x|/t)^{-N-1-\varepsilon} \\ &\leq c\psi_t(x)|Q(x)|^{-1}, \end{aligned}$$

since $|Q(x)| \sim |x|^N$ for large $|x|$. This implies the claim, and the corresponding part of $\|f(x, t)\|_{1,u}$ can be easily estimated as before. This completes the first step of the proof.

Pick $g \in C^\infty$ with compact support away from the zeros of Q and $\|f - g\|_{1,u}$ small. That such g exists follows from the local integrability of u : in fact, we may successively approximate f by bounded functions with compact support away from the zeros of Q , continuous functions with such support, functions that are polynomials on the intervals on which they are supported, and finally functions g of the type desired. To complete the proof, we may assume $f\phi = 1$ and show that $f(x, t) \rightarrow f(x)$ in L_u^1 . We have

$$\begin{aligned} & \|f(x, t) - f(x)\|_{1,u} \\ & \leq \|f(x, t) - g(x, t)\|_{1,u} + \|g(x, t) - g(x)\|_{1,u} + \|g(x) - f(x)\|_{1,u} \\ & \leq 2\|f(x) - g(x)\|_{1,u} + \|g(x, t) - g(x)\|_{1,u} \end{aligned}$$

by (6.4), and it is enough to show $g(x, t) \rightarrow g(x)$ in norm.

We will first show that $g(x, t)$ converges uniformly to $g(x)$ on compact sets away from the zeros of Q . Write

$$g(x, t) = \int_{\mathbf{R}} g(z) \phi_t(x - z) dz - \int_{\mathbf{R}} g(z) \mathcal{P}_{\phi_t(x-\cdot)}(z) dz.$$

The first term on the right converges uniformly to $g(x)$ on compact sets. In the second term,

$$|\mathcal{P}_{\phi_t(x-\cdot)}(z)| \leq c \max_{k; 0 \leq \alpha < \mu_k} |\phi_t^{(\alpha)}(x - a_k)|$$

since $|z - a_k| \geq c > 0$ for all k if $g(z) \neq 0$. If x is also bounded away from every a_k ,

$$|\mathcal{P}_{\phi_t(x-\cdot)}(z)| \leq c \max_{0 \leq \alpha < N} t^{-\alpha-1} (1 + t^{-1})^{-\alpha-1-\epsilon} \leq ct^\epsilon,$$

and therefore the second term above converges uniformly to zero away from the a_k 's as $t \rightarrow 0$. It follows that the part of $\|g(x, t) - g(x)\|_{1,u}$ with x in a compact set away from the a_k 's tends to zero with t .

The part of $\|g(x, t) - g(x)\|_{1,u}$ with x in a small neighborhood of some a_k is at most

$$\int_{|x-a_k|<\delta} |g(x, t)| |Q(x)| w(x) dx + \int_{|x-a_k|<\delta} |g(x)| |Q(x)| w(x) dx.$$

The second term is independent of t and small with δ . To estimate the first term, note that if $g(z) \neq 0$ then z is bounded and away from all the a_k 's. Since x is very near a_k ,

$$\begin{aligned} |\phi_t(x - z) - \mathcal{P}_{\phi_t(x-\cdot)}(z)| & \leq c \left[1 + \max_{j; 0 \leq \alpha < \mu_j} |\phi_t^{(\alpha)}(x - a_j)| \right] \\ & \leq c \max_{0 \leq \alpha < \mu_k} |x - a_k|^{-\alpha-1} \leq c |Q(x)|^{-1}. \end{aligned}$$

Hence, $|g(x, t)| \leq c \|g\|_1 |Q(x)|^{-1}$, and the first term above is bounded uniformly in t by $c \int_{|x-a_k|<\delta} w(x) dx$, which is small with δ .

Finally, for $|x|$ large and $|z|$ bounded, as noted in the first half of the proof,

$$|\phi_t(x - z) - \mathcal{P}_{\phi_t(x-\cdot)}(z)| \leq c \psi_t(x) |Q(x)|^{-1}.$$

Hence, $|g(x, t)| \leq c \psi_t(x) |Q(x)|^{-1}$ for large $|x|$. Since $g(x) = 0$ for $|x| > M$, the part of $\|g(x, t) - g(x)\|_{1,u}$ with $|x| > M$ is at most

$$c \int_{|x| > M} \psi_t(x) w(x) dx \leq ct^\epsilon \int_{|x| > M} \frac{w(x)}{|x|^{1+\epsilon}} dx.$$

This tends to zero with t , and the proof is complete.

7. Theorem 3. In this section, we prove Theorem 3 and identify the embeddings of L_u^p in H_u^p which are the identity on H_u^p . Let $1 < p < \infty$, d be a positive integer and $u = (1 + x^2)^{d/2} |Q|^p w$, where Q has all real zeros and $w \in A_p$.

First observe that $\|fQx^i\|_{L^1} \leq c\|f\|_{p,u}$, $i = 0, \dots, d-1$, since by Hölder's inequality,

$$\begin{aligned} \|fQx^i\|_{L^1} &\leq \|f\|_{p,u} \|x^i w(x)^{-1/p} (1 + |x|^2)^{-d/2}\|_{p'} \\ (7.1) \quad &\leq \|f\|_{p,u} \|w(x)^{-1/p} (1 + |x|)^{-1}\|_{p'} = c\|f\|_{p,u}, \end{aligned}$$

$i = 0, \dots, d-1$. This shows that the moments $\int_{\mathbf{R}} fQx^i dx$, $i = 0, \dots, d-1$, are finite if $f \in L_u^p$.

If $f \in L_u^p$, then f belongs to both $L_{|Q|^p w}^p$ and $L_{|x^d Q|^p w}^p$. By Theorem 2, it follows that f corresponds to $l_1 \in H_{|Q|^p w}^p$ and $l_2 \in H_{|x^d Q|^p w}^p$:

$$\begin{aligned} \langle l_1, \phi \rangle &= \int_{\mathbf{R}} f(z) [\phi(z) - \mathfrak{P}_\phi^Q(z)] dz, \\ \langle l_2, \phi \rangle &= \int_{\mathbf{R}} f(z) [\phi(z) - \mathfrak{P}_\phi^{x^d Q}(z)] dz, \\ \|l_1\|_{H_{|Q|^p w}^p} &\leq c\|f\|_{L_u^p}, \quad \|l_2\|_{H_{|x^d Q|^p w}^p} \leq c\|f\|_{L_u^p}. \end{aligned}$$

Thus,

$$\begin{aligned} \langle l_1, \phi \rangle - \langle l_2, \phi \rangle &= \int_{\mathbf{R}} f(z) [\mathfrak{P}_\phi^{x^d Q}(z) - \mathfrak{P}_\phi^Q(z)] dz \\ &= \sum_{i=0}^{d-1} \mathfrak{P}^{x^{i+1} Q}(\phi) \int_{\mathbf{R}} f(z) Q(z) z^i dz \end{aligned}$$

by (2.8). Assuming that the moments of fQ of order $0, \dots, d-1$ vanish gives $l_1 = l_2$. Calling this common value l , we see that l belongs to both $H_{|Q|^p w}^p$ and $H_{|x^d Q|^p w}^p$, and therefore to H_u^p with $\|l\|_{H_u^p} \leq c\|f\|_{L_u^p}$.

Conversely, if $l \in H_u^p$, the nontangential maximal function of l belongs to both $L_{|Q|^p w}^p$ and $L_{|x^d Q|^p w}^p$. By Theorem 2, there exist f and g , $\|f\|_{L_{|Q|^p w}^p} \leq c\|l\|_{H_u^p}$, $\|g\|_{L_{|x^d Q|^p w}^p} \leq c\|l\|_{H_u^p}$, such that

$$\langle l, \phi \rangle = \int_{\mathbf{R}} f(z) [\phi(z) - \mathfrak{P}_\phi^Q(z)] dz, \quad \langle l, \phi \rangle = \int_{\mathbf{R}} g(z) [\phi(z) - \mathfrak{P}_\phi^{x^d Q}(z)] dz.$$

Choosing ϕ to vanish near the zeros of $x^d Q$, we obtain $\mathfrak{P}_\phi^{x^d Q} = \mathfrak{P}_\phi^Q = 0$ and $\int_{\mathbf{R}} f(z) \phi(z) dz = \int_{\mathbf{R}} g(z) \phi(z) dz$. Therefore, $f = g$ a.e., $\|f\|_{L_u^p} \leq c\|l\|_{L_u^p}$, and if we take the difference of the two formulas for $\langle l, \phi \rangle$ we obtain

$$\int_{\mathbf{R}} f(z) [\mathfrak{P}_\phi^{x^d Q}(z) - \mathfrak{P}_\phi^Q(z)] dz = 0, \quad \phi \in \mathcal{S}.$$

Pick $\rho \in \mathfrak{S}$, $\rho(x) = 1$ near the support of $\mathfrak{Q}^{x^d}Q$, and let $\phi(x) = x^i Q(x)\rho(x)$, $i = 0, \dots, d-1$. Then

$$\mathfrak{P}_\phi^{x^d Q}(z) - \mathfrak{P}_\phi^Q(z) = \mathfrak{P}_{x^i Q}^{x^d Q}(z) - \mathfrak{P}_{x^i Q}^Q(z) = z^i Q(z) - 0 = z^i Q(z)$$

by Lemma (2.5)(i) and (ii). Therefore, $\int_{\mathbf{R}} f(z) z^i Q(z) dz = 0$, $i = 0, \dots, d-1$, and the theorem follows.

Theorem 3 is valid for $Q \equiv 1$ if we adopt the convention that the interpolating polynomial $\mathfrak{P}_\phi^Q$ is zero in this case. This follows by checking the proof. Note that a function f satisfies $f \in L_{(1+x^2)^{dp/2}|Q|^{pw}}^p$ with the moments of fQ up to order at least $d-1$ all zero if and only if the function $g = fQ$ satisfies $g \in L_{(1+x^2)^{dp/2}w}^p$ with the moments of g up to order at least $d-1$ all equal to zero. Hence, we obtain the following (cf. Corollary (5.6)).

COROLLARY (7.2). *Let $1 < p < \infty$, d be a positive integer, Q be a polynomial with all real zeros and $w \in A_p$. If $f \in L_{(1+|x|^2)^{dp/2}|Q|^{pw}}^p$ and the moments of fQ of order $0, \dots, d-1$ all vanish, then*

$$\left\| \sup_{\Gamma_\gamma(x)} \left| \int_{\mathbf{R}} f(z) \left[\phi_t(y-z) - \mathfrak{P}_{\phi_t(y-\cdot)}^Q(z) \right] dz \right| \right\|_{L_{(1+|x|^2)^{dp/2}|Q|^{pw}}^p}$$

and

$$\left\| \sup_{\Gamma_\gamma(x)} \left| \int_{\mathbf{R}} f(z) Q(z) \phi_t(y-z) dz \right| \right\|_{L_{(1+|x|^2)^{dp/2}w}^p}$$

are equivalent if $\phi \in \mathfrak{S}$, $\int \phi = 1$.

COROLLARY (7.3). *Under the same assumptions as in Theorem 3, there is a continuous linear embedding $f \rightarrow f - k_f$ of L_u^p onto H_u^p which is the identity on H_u^p and which satisfies*

$$\int_{\mathbf{R}} k_f Q x^i dx = \int_{\mathbf{R}} f Q x^i dx, \quad i = 0, \dots, d-1.$$

Conversely, any continuous linear embedding of L_u^p in H_u^p which is the identity on H_u^p has this form.

PROOF. As noted in (7.1), $\|fQx^i\|_{L^1} \leq c\|f\|_{p,u}$ for $i = 0, \dots, d-1$. Pick $\eta_i \in \mathfrak{S}$, $i = 0, \dots, d-1$, with $\int_{\mathbf{R}} \eta_i(x) Q(x) x^j dx = \delta_{ij}$, where δ_{ij} is the Kronecker δ . That such η_i exist can be seen as follows. First, we use Lemma 2.6, p. 182 of [2] to pick $\nu_i \in C_0^\infty$ with support away from the zeros of Q such that $\int_{\mathbf{R}} \nu_i(x) x^j dx = \delta_{ij}$, and then we set $\eta_i = \nu_i/Q$. Let

$$g_f(x) = \sum_{i=0}^{d-1} \eta_i(x) \int_{\mathbf{R}} f(t) Q(t) t^i dt.$$

Then $\|g_f\|_{p,u} \leq c\|f\|_{p,u}$ and $\int_{\mathbf{R}} g_f Q x^i dx = \int_{\mathbf{R}} f Q x^i dx$, $i = 0, \dots, d-1$. Hence, $f - g_f \in L_u^p$ with $\|f - g_f\|_{p,u} \leq c\|f\|_{p,u}$, and the first $d-1$ moments of $(f - g_f)Q$ vanish. Therefore, $f - g_f \in H_u^p$ by Theorem 3, and since $g_f = 0$ if $f \in H_u^p$ by

Theorem 3 again, the mapping $f \rightarrow f - g_f$ is an embedding of L_u^p into H_u^p which is the identity H_u^p .

Conversely, let S be any embedding of L_u^p in H_u^p which is the identity on H_u^p . If $f \in L_u^p$, choose g_f as above. Then $f - g_f \in H_u^p$, so $S(f - g_f) = f - g_f$, $Sf = f - (g_f - Sg_f)$. The function $g_f - Sg_f$ belongs to L_u^p with norm bounded by a multiple of the norm of f , and for $i = 0, \dots, d-1$,

$$\begin{aligned} \int_{\mathbf{R}} (g_f - Sg_f) Qx^i dx &= \int_{\mathbf{R}} g_f Qx^i dx - \int_{\mathbf{R}} Sg_f Qx^i dx \\ &= \int_{\mathbf{R}} f Qx^i dx - 0 = \int_{\mathbf{R}} f Qx^i dx, \end{aligned}$$

by Theorem 3 since $Sg_f \in H_u^p$. This completes the proof.

8. Density theorems.

THEOREM (8.1). *Let Q be a polynomial with all real zeros. If $1 \leq p < \infty$ and $w(x)(1 + |x|)^{-M}$ is integrable for some M , then the class of $g \in \mathfrak{S}$ with $\int_{\mathbf{R}} g(x)x^j dx = 0$ for $j = 0, \dots, N-1$ is dense in L_u^p , $u = |Q|^p w$.*

PROOF. Since $w(x)(1 + |x|)^{-M}$ is integrable, $\mathfrak{S} \subset L_u^p$. Since u is locally integrable, $\mathfrak{S}$ is dense in L_u^p (see the related statement for $p = 1$ in the proof of Theorem (6.3)). Hence, it is enough to show that functions in $\mathfrak{S}$ can be approximated in L_u^p by such g .

Let $P_{k,l}(x)$ be the polynomials of degree $N-1$ with

$$(8.2) \quad \mathcal{P}_\phi^Q(x) = Q(x) \mathcal{Q}_y \left(\frac{\phi(y)}{x-y} \right) = \sum_{k=1}^n \sum_{l=1}^{\mu_k} \frac{\phi^{(l-1)}(a_k)}{(l-1)!} P_{k,l}(x), \quad \phi \in \mathfrak{S}.$$

The $P_{k,l}$ of course depend on Q but are independent of ϕ . Moreover, for $k' \neq k$, $P_{k,l}(x)$ has a zero of order $\mu_{k'}$ at $x = a_{k'}$. Let $\eta_i(x)$, $i = 1, \dots, N$, be C^∞ functions supported in $[-1, 1]$ with $\int_{\mathbf{R}} \eta_i(x)x^{j-1} dx = \delta_{ij}$, $j = 1, \dots, N$, where δ_{ij} is the Kronecker δ : that such η_i exist was noted in the proof of Corollary (7.3). Given $f \in \mathfrak{S}$, let

$$(8.3) \quad \begin{aligned} c_{k,l} &= \int_{\mathbf{R}} f(x) P_{k,l}(x) dx, \quad k = 1, \dots, n, l = 1, \dots, \mu_k, \\ f_r(x) &= f(x) - \sum_{k=1}^n \sum_{l=1}^{\mu_k} c_{k,l} \eta_l \left(\frac{x-a_k}{r} \right) r^{-l}, \quad r > 0. \end{aligned}$$

We claim that $f_r \in \mathfrak{S}$, $\int_{\mathbf{R}} f_r(x)x^j dx = 0$ for $j = 0, \dots, N-1$, and f_r converges to f in L_u^p as $r \rightarrow 0$. That $f_r \in \mathfrak{S}$ is obvious. For the norm convergence, it is enough to show that

$$\int_{\mathbf{R}} \left| \eta_l \left(\frac{x-a_k}{r} \right) r^{-l} Q(x) \right|^p w(x) dx \rightarrow 0$$

as $r \rightarrow 0$ for $k = 1, \dots, n$ and $l = 1, \dots, \mu_k$. But $\eta_l((x-a_k)/r)$ is supported in $|x-a_k| < r$, where $|Q(x)| \leq cr^{\mu_k}$. Hence, the last integral is at most $cr^{(\mu_k-l)p} \int_{|x-a_k| < r} w(x) dx$, which tends to zero with r since $\mu_k - l \geq 0$.

To show $\int_{\mathbf{R}} f_r(x) x^j dx = 0$ for $j = 0, \dots, N-1$, note that $\{P_{k,l}(x)\}_{k,l}$ spans the space of polynomials $P(x)$ of degree at most $N-1$: in fact, by Lemma (2.5)(i) and (8.2),

$$(8.4) \quad P(x) = \mathcal{G}_P^Q(x) = \sum_{k=1}^n \sum_{l=1}^{\mu_k} \frac{P^{(l-1)}(a_k)}{(l-1)!} P_{k,l}(x)$$

for such P . Thus, it is enough to show that

$$(8.5) \quad \int_{\mathbf{R}} f_r(x) P_{k',l'}(x) dx = 0$$

for $k' = 1, \dots, n$, $l' = 1, \dots, \mu_{k'}$. We have

$$\begin{aligned} & \int_{\mathbf{R}} f_r(x) P_{k',l'}(x) dx \\ &= \int_{\mathbf{R}} f(x) P_{k',l'}(x) dx - \sum_{k=1}^n \sum_{l=1}^{\mu_k} c_{k,l} \int_{\mathbf{R}} P_{k',l'}(x) \eta_l\left(\frac{x-a_k}{r}\right) r^{-l} dx \\ &= c_{k',l'} - \sum_{k=1}^n \sum_{l=1}^{\mu_k} c_{k,l} \int_{\mathbf{R}} P_{k',l'}(x) \eta_l\left(\frac{x-a_k}{r}\right) r^{-l} dx. \end{aligned}$$

We will show that for $k = 1, \dots, n$ and $l = 1, \dots, \mu_k$,

$$\int_{\mathbf{R}} P_{k',l'}(x) \eta_l\left(\frac{x-a_k}{r}\right) r^{-l} dx = \delta_{kk'} \delta_{ll'},$$

from which (8.5) follows. Let $\tau_{k,l}(x) = \eta_l((x-a_k)/r)r^{-l}$. Changing variables and using the definition of η_l , we obtain

$$(8.6) \quad \int_{\mathbf{R}} \tau_{k,l}(x) (x-a_k)^{j-1} dx = \delta_{l,j},$$

$k = 1, \dots, n$, $l = 1, \dots, N$, $j = 1, \dots, N$. As noted earlier, if $k' \neq k$, $P_{k',l'}$ has a zero of order μ_k at a_k , i.e.,

$$P_{k',l'}(x) = \sum_{j > \mu_k} b_{k',l',j} (x-a_k)^{j-1}, \quad k' \neq k.$$

Therefore, if $k' \neq k$ and $l = 1, \dots, \mu_k$, (8.6) implies

$$(8.7) \quad \int_{\mathbf{R}} P_{k',l'}(x) \tau_{k,l}(x) dx = 0.$$

If $k' = k$, (8.4) gives

$$(x-a_k)^{l'-1} = \sum_{\substack{k''=1 \\ k'' \neq k}}^n \sum_{l''=1}^{\mu_{k''}} \alpha_{k'',l''} P_{k'',l''}(x) + P_{k,l'}(x).$$

Thus,

$$\begin{aligned} & \int_{\mathbf{R}} P_{k,l'}(x) \tau_{k,l}(x) dx \\ &= \int_{\mathbf{R}} (x - a_k)^{l'-1} \tau_{k,l}(x) dx - \sum_{\substack{k'',l'' \\ k'' \neq k}} \alpha_{k'',l''} \int_{\mathbf{R}} P_{k'',l''}(x) \tau_{k,l}(x) dx \\ &= \delta_{ll'} - 0 = \delta_{ll'} \end{aligned}$$

by (8.6) and (8.7). This completes the proof of the theorem.

The conclusion of Theorem (8.1) can be obtained in another way under the stronger assumptions that $1 \leq p < \infty$ and $w \in A_p$. As noted at the beginning of the proof of (8.1), it is enough to show that functions in $\mathfrak{S}$ can be approximated in L_u^p by functions in $\mathfrak{S}$ whose moments up to order $N - 1$ vanish. Consider the extension of f defined in Theorem 1:

$$f_t(x) = \int_{\mathbf{R}} f(z) \left[\phi_t(x - z) - \mathfrak{P}_{\phi_t(x-\cdot)}^Q(z) \right] dz.$$

If $f, \phi \in \mathfrak{S}$, it follows from the definition of $\mathfrak{P}$ that $f_t \in \mathfrak{S}$. Moreover, by Corollary (5.5) (or Lemma (2.6) when $p = 1$), f_t satisfies the required moment condition, and if we choose ϕ with $\int_{\mathbf{R}} \phi = 1$, then by Theorem (6.3), f_t converges to f in norm as $t \rightarrow 0$. Thus, f_t satisfies all the requirements.

THEOREM (8.8). *Let Q be a polynomial with all real zeros. If $1 \leq p < \infty$ and*

$$(8.9) \quad \lim_{m \rightarrow \infty} \frac{1}{m^p} \int_{-m}^m w(x) dx = 0,$$

then $\mathfrak{S}_{0,0}$ is dense in L_u^p , $u = |Q|^p w$.

For the proof we need the following fact.

LEMMA (8.10). *Let $1 \leq p < \infty$, i be a nonnegative integer, and u be a nonnegative function with*

$$\lim_{m \rightarrow \infty} \frac{1}{m^{(i+2)p}} \int_{-m}^m u(x) dx = 0.$$

If $f \in \mathfrak{S}$ and $\int_{\mathbf{R}} f(x) x^j dx = 0, j = 0, \dots, i$, then there is a sequence of functions in $\mathfrak{S}_{0,0}$ which converges to f in L_u^p .

This is a special case of Theorem 6.13 of [7].

To prove Theorem (8.8), first note (8.9) implies that for $m \geq 0$,

$$\int_{2^m \leq |x| \leq 2^{m+1}} \frac{w(x)}{|x|^M} dx \leq c(2^m)^{p-M}.$$

Adding these inequalities for $m \geq 0$ and using the local integrability of w shows that $w(x)(1 + |x|)^{-M}$ is integrable for $M > p$. To complete the proof, we only need to

combine Theorem (8.1) with Lemma (8.10) for $i = N - 1$ and $u = |Q|^p w$, noting that

$$\frac{1}{m^{(N+1)p}} \int_{-m}^m |Q(x)|^p w(x) dx \leq \frac{c}{m^p} \int_{-m}^m w(x) dx \rightarrow 0$$

as $m \rightarrow \infty$ by (8.9).

COROLLARY (8.11). *Let Q be a polynomial with all real zeros, $1 < p < \infty$, $w \in A_p$ and $u = |Q|^p w$. Then $\mathfrak{S}_{0,0}$ is dense in L_u^p .*

PROOF. Since $w \in A_p$, it satisfies the doubling condition of order p ,

$$\int_{-m}^m w(x) dx \leq cm^p \int_{-1}^1 w(x) dx, \quad m > 1.$$

If $p > 1$, the fact that $w \in A_{p-\varepsilon}$ for some $\varepsilon > 0$ (see [6]) then implies that (8.9) holds, and the corollary follows.

The density theorems above have analogues for L_u^p when u has the form $u = (1 + |x|^2)^{dp/2} |Q|^p w$ where d is a positive integer.

THEOREM (8.12). *Let $1 \leq p < \infty$, d be a positive integer and $u = (1 + |x|^2)^{dp/2} |Q|^p w$, where w is a nonnegative function such that $w(x)(1 + |x|)^{-M}$ is integrable for some M and $w(x)^{-1/p}(1 + |x|)^{-1} \in L^{p'}$. Then the class of g in $\mathfrak{S}$ with $\int_{\mathbf{R}} g(x)x^j dx = 0$ for $j = 0, \dots, N + d - 1$ is dense in the subspace of L_u^p of f with $\int_{\mathbf{R}} fQx^i dx = 0$ for $i = 0, \dots, d - 1$.*

We remark that the assumptions on w are true if $w \in A_p$.

PROOF. Recall from (7.1) that $\|fQx^i\|_{L^1} \leq c\|f\|_{L_u^p}$, $i = 0, \dots, d - 1$.

This shows that the moments $\int_{\mathbf{R}} fQx^i dx$, $i = 0, \dots, d - 1$, are finite if $f \in L_u^p$ and that if $f_n \rightarrow f$ in L_u^p , then

$$\int_{\mathbf{R}} f_n Qx^i dx \rightarrow \int_{\mathbf{R}} f Qx^i dx, \quad i = 0, \dots, d - 1.$$

We first show that if $f \in L_u^p$ and $\int_{\mathbf{R}} fQx^i dx = 0$, $i = 0, \dots, d - 1$, then f can be approximated in L_u^p by $g \in \mathfrak{S}$ with $\int_{\mathbf{R}} gQx^i dx = 0$, $i = 0, \dots, d - 1$. In fact, pick $f_n \in \mathfrak{S}$ with $f_n \rightarrow f$ in L_u^p , and let

$$g_n(x) = f_n(x) - \sum_{i=0}^{d-1} \eta_i(x) \int_{\mathbf{R}} f_n(t) Q(t) t^i dt,$$

where $\{\eta_i\}$ is chosen with $\eta_i \in \mathfrak{S}$ and $\int_{\mathbf{R}} \eta_i(x) Q(x) x^j dx = \delta_{ij}$. (See the proof of Corollary (7.3).) Clearly, $g_n \in \mathfrak{S}$ and

$$\int_{\mathbf{R}} g_n Qx^j dx = \int_{\mathbf{R}} f_n Qx^j dx - \int_{\mathbf{R}} f_n Q t^j dt = 0,$$

$j = 0, \dots, d - 1$. Moreover, the facts that $f_n \rightarrow f$ in L_u^p , $\eta_i \in L_u^p$ and $\int_{\mathbf{R}} f_n Q t^i dt \rightarrow \int_{\mathbf{R}} f Q t^i dt = 0$, $i = 0, \dots, d - 1$, show that $g_n \rightarrow f$ in L_u^p , as desired.

Thus, it is enough to prove the theorem for $f \in \mathfrak{S}$. Let g_r be the function f_r defined in (8.3) but now formed using $x^d Q(x)$ as generating polynomial. Then, as shown in the proof of Theorem (8.1), $g_r \in \mathfrak{S}$, the moments of g_r of order $\leq N + d - 1$ vanish, and $g_r \rightarrow f$ in $L_{|x^d Q|^p w}^p$ as $r \rightarrow 0$. Since $u \leq c[|Q|^p w + |x^d Q|^p w]$, the proof of the theorem will be complete if we show that g_r also converges to f in $L_{|Q|^p w}^p$. Let f_r

denote the function in (8.3) formed with Q as generator and the same $\{\eta_i\}$ as for g_r . Then $f_r \rightarrow f$ in $L_{|Q|^p w}^p$, so we will be done if we show that $f_r = g_r$. However, it follows easily from (8.2) and (2.8) that those polynomials $P_{k,l}$ for $x^d Q$ with $k = 1, \dots, n$, $l = 1, \dots, \mu_k$, differ from the corresponding $P_{k,l}$ for Q by linear combinations of the $x^j Q$, $j = 0, \dots, d-1$, while those $P_{k,l}$ for $x^d Q$ with $k > n$ or $l > \mu_k$ are linear combinations of the $x^j Q$. Hence, since $\int_{\mathbf{R}} f x^j Q dx = 0$ for $j = 0, \dots, d-1$, we obtain $f_r = g_r$.

THEOREM (8.13). *Let $1 \leq p < \infty$, d be a positive integer and*

$$u = (1 + |x|^2)^{d/2} |Q|^p w,$$

where w is a nonnegative function such that $w(x)^{-1/p}(1 + |x|)^{-1}$ is in $L^{p'}$ and (8.9) holds. Then $\mathfrak{S}_{0,0}$ is dense in the subspace of L_u^p of f with $\int_{\mathbf{R}} f Q x^i dx = 0$ for $i = 0, \dots, d-1$.

PROOF. This follows from the previous theorem by using Lemma (8.10), with i there taken to be $N + d - 1$, in the same way that Theorem (8.8) follows from Theorem (8.1).

COROLLARY (8.14). *If $1 < p < \infty$, d is a positive integer and $u = (1 + |x|^2)^{d/2} |Q|^p w$ with $w \in A_p$, then $\mathfrak{S}_{0,0}$ is dense in the subspace of L_u^p of f with $\int_{\mathbf{R}} f Q x^i dx = 0$ for $i = 0, \dots, d-1$. In particular, the closure of $\mathfrak{S}_{0,0}$ in L_u^p is this subspace.*

PROOF. The first statement follows as in the proof of Corollary (8.11). For the second, note that if f is in the closure of $\mathfrak{S}_{0,0}$, then there exist f_n in $\mathfrak{S}_{0,0}$ such that $f_n \rightarrow f$ in L_u^p , and therefore, $\int_{\mathbf{R}} f_n Q x^i dx \rightarrow \int_{\mathbf{R}} f Q x^i dx$, $i = 0, \dots, d-1$. Since the integrals on the left all vanish, so does the one on the right.
