# UNITAL $l$-PRIME LATTICE-ORDERED RINGS WITH POLYNOMIAL CONSTRAINTS ARE DOMAINS 

BY<br>STUART A. STEINBERG ${ }^{1}$

To Nathan Jacobson

#### Abstract

It is shown that a unital lattice-ordered ring in which the square of every element is positive must be a domain provided the product of two nonzero $l$-ideals is nonzero. More generally, the same conclusion follows if the condition $a^{2} \geqslant 0$ is replaced by $p(a) \geqslant 0$ for suitable polynomials $p(x)$; and if it is replaced by $f(a, b) \geqslant 0$ for suitable polynomials $f(x, y)$ one gets an $l$-domain. It is also shown that if $a \wedge b=0$ in a unital lattice-ordered algebra which satisfies these constraints, then the $l$-ideals generated by $a b$ and $b a$ are identical.

1. Introduction. In [5, p. 79] Diem has asked if an $l$-prime $l$-ring in which the square of every element is positive is an $l$-domain. In this paper we show that any such $l$-ring $R$ is a domain provided the $f$-subring $T$ of $f$-elements has zero annihilator in $R$ or the $T-T$ convex $l$-bimodule of $R$ generated by $T a+a T$ contains $a$ for each nilpotent element $a$ of index 2. Also, some polynomial constraints which generalize the condition that squares are positive are considered, and it is shown that an $l$-prime $l$-ring with such constraints is an $l$-domain, sometimes even a domain. Our original arguments were based on Lemmas 13 and (an earlier version of) 14. However, while this paper was being revised we realized that the simpler Lemma 2 was sufficient to get $l$-domains from $l$-prime $l$-rings.

A lattice-ordered ring ( $l$-ring) is a ring $R$ whose additive group is an l-group (that is, $R$ is a lattice and each translation $x \rightarrow a+x$ is order preserving, and hence is an order automorphism) and in which the set of positive elements $R^{+}=\{a \in R$ : $a \geqslant 0\}$ is closed under multiplication. Some good references for background material on $l$-rings are $[4 ; 2 ; 3$, Chapters 13 and $17 ; 6 ; 9$, Chapter I, pp. 164-176 and 14, $\S 2$, pp. 192-202]. In particular, in Theorem 1 of [14] and Proposition 1.3 of [9] there is a list of many of the basic equations, inequalities and properties that result from the interaction of the lattice and ring structures in an $l$-ring.

[^0]The right (left) module $M$ over the $l$-ring $R$ is called an l-module if $M$ is an l-group and $M^{+} R^{+} \subseteq M^{+}\left(R^{+} M^{+} \subseteq M^{+}\right)$. A convex $l$-subgroup (submodule) of $M$ is a subgroup (submodule) $X$ that is a sublattice which is also convex: $x \leqslant m \leqslant y$ and $x$, $y \in X$ imply $m \in X$; that is, $X$ is the kernel of an l-group ( $l$-module) homomorphism. The element $r \in R^{+}$is an f-element on $M_{R}$ if for all $a, b \in M$
(1) $a \wedge b=0$ implies $a r \wedge b=0$.

If $R^{+}$consists of $f$-elements on $M$, then $M$ is called an $f$-module over $R$. An $l$-module over $R$ is an $f$-module precisely when it is embeddable in a product of totally ordered $R$-modules [13, Theorem 1.1 or $1, \mathrm{p} .54]$. Note that when $M_{R}$ is an $f$-module, the map $x \rightarrow x r$ is a lattice homomorphism of $M$ for each $r \in R^{+}$(see, for example [4, Lemma 1 , p. 52 or 2 , Theorem 1.4 .4, p. 25]). If $R$ and $S$ are $l$-rings, then $M$ is an $R-S$ $l$-bimodule ( $f$-bimodule) if $M$ is a left $l$-module ( $f$-module) over $R$, a right $l$-module ( $f$-module) over $S$ and $r(x s)=(r x) s$ for all $r \in R, x \in M$, and $s \in S$. The $R-S$ $l$-bimodule is an $f$-bimodule if and only if it is embeddable in a product of totally ordered $R$-S $l$-bimodules. In particular, $R$ is an $f$-ring (that is, $R$ is an $R-R$ $f$-bimodule) precisely when it is embeddable in a product of totally ordered rings [4, Theorem 12, p. 57]. By an f-element of the l-ring $R$ we mean an element $a \in R^{+}$ which is an $f$-element on both the $l$-modules $R_{R}$ and ${ }_{R} R$. An $l$-algebra over the commutative unital totally ordered domain $F$ is a ring $R$ which is a torsion-free algebra over $F$ and which is also an $f$-module over $F$. Of course, any $l$-ring $R$ is an $l$-algebra over the integers $\mathbf{Z}$; and if $R$ is also an $l$-module and algebra over the totally ordered field $F$, then it is an $l$-algebra over $F$.

An (right, left) ideal of the $l$-ring $R$ is an (right, left) l-ideal of $R$ if it is also a convex $l$-subgroup of the additive $l$-group of $R . R$ is called $l$-prime if the product of two nonzero $l$-ideals is nonzero, and $R$ is an $l$-domain if the product of two nonzero positive elements is nonzero. $R$ is called (l-reduced) reduced if it has no nonzero (positive) nilpotent elements, and $l$-semiprime if it has no nonzero nilpotent $l$-ideals. Recall that $R$ is $l$-semiprime ( $l$-prime) if and only if for all $a \in R^{+}\left(a, b \in R^{+}\right)$, $a R a=0(a R b=0)$ implies $a=0(a=0$ or $b=0)[5,2.5$, p. 73 or 11$]$. An $l$-ideal $P$ is an l-prime l-ideal of $R$ if $R / P$ is an $l$-prime $l$-ring. By the lower $l$-radical of the $l$-ring $R$ we mean $\beta(R)=$ the intersection of all the $l$-prime $l$-ideals of $R$. The lower $l$-radical is a nil $l$-ideal, and $R$ is $l$-semiprime if and only if $\beta(R)=0[5,2.13$ or 11$]$. We also note that, just as for rings, an $l$-reduced $l$-prime $l$-ring is an $l$-domain. Birkhoff and Pierce [4, p. 63] have shown:
(2) If $R$ is an $f$-ring, then $N_{n}=\left\{a \in R: a^{n}=0\right\}$ is a nilpotent $l$-ideal of index at most $n$.

Let $R$ be an $l$-algebra over $F$, and let $I$ be an $l$-ideal of $R$. Then $I_{1}=\{x \in R$ : $|x| \leqslant \alpha i$ for some $\alpha \in F^{+}$and $\left.i \in I^{+}\right\}$is the algebra $l$-ideal of $R$ generated by $I$. Since $I_{1}^{2} \subseteq I$, if $I$ is an $l$-prime $l$-ideal, then it is an algebra ideal. So $\beta(R)$ is the lower $l$-radical of the $l$-algebra $R$.

If $a$ is an element of the $l$-module $M$, then its positive part, negative part and absolute value are defined by $a^{+}=a \vee 0, a^{-}=(-a) \vee 0$ and $|a|=a \vee(-a)$, respectively. Then $a=a^{+}-a^{-},|a|=a^{+}+a^{-}$and $a^{+} \wedge a^{-}=0$. Moreover, if $a \wedge b=0$, then $a=x^{+}$and $b=x^{-}$for $x=a-b$. So for an $l$-ring $R$ (1) is equivalent to the
identity $x^{+} y^{+} \wedge x^{-}=0$. Since $y^{+} x^{+} \wedge x^{-}=0$ is the corresponding identity for ${ }_{R} R$, the class of $f$-rings is a variety of $l$-rings. Also, each of the following conditions is equivalent to the corresponding parenthetical identity, and hence determines a variety of $l$-rings:
(3) $a \wedge b=0$ implies $a b=0\left(x^{+} x^{-}=0\right)$.
(4) $a^{2} \geqslant 0$ for each $a$ in $R\left(\left(x^{2}\right)^{-}=0\right)$.

The variety of $f$-rings is contained in the variety determined by (3); and the latter is contained in that determined by (4): $a^{2}=\left(a^{+}-a^{-}\right)^{2}=\left(a^{+}\right)^{2}+\left(a^{-}\right)^{2} \geqslant 0[4, \mathrm{p}$. 59]. Johnson [ 9, p. 174] has shown that an $l$-prime $f$-ring is a totally ordered domain (also see [10]), and Diem [5, p. 81] has shown that an $l$-prime $l$-ring which satisfies (3) is also a totally ordered domain (see Lemma 13 below).

Let $F[x, y]$ be a free noncommutative algebra over the totally ordered domain $F$. As a generalization of squares positive, a torsion-free $l$-algebra $R$ over $F$ is called a PPI l-algebra if there is a polynomial $f(x, y) \in F[x, y]$ such that $f(a, b) \geqslant 0$ for each $a, b \in R$ (we do not have any occasion to use more than two variables). Of course, we assume that $f(x, y) \notin F$, and if $R$ is not unital, then the constant term of $f(x, y)$ is zero. If for each $a$ in the $l$-algebra $R$ there is a polynomial $p(x)$ in $F[x]$ (of positive degree) with $p(a) \in R^{+}$, then $R$ will be called p-positive. A PPI $l$-algebra which satisfies $p(x) \geqslant 0$ is $p$-positive. In $\S 3$ we show that a unital $l$-prime $p$-positive $l$-algebra with properly conditioned polynomials is an $l$-domain, or even a domain.

In [12] Shyr and Viswanathan have called an $l$-ring $R$ square-archimedean if for each $a, b \in R^{+}$there is a positive integer $n$ such that $a b+b a \leqslant n\left(a^{2}+b^{2}\right)$. They showed that in a square archimedean $l$-ring $R, \beta(R)$ is the sum of the nilpotent $l$-ideals of $R$, and it is the largest nil l-ideal of $R$. In §3 we consider polynomials more general than $f(x, y)=-(x y+y x)+n\left(x^{2}+y^{2}\right)$. We show that if $R$ is an $l$-prime $l$-algebra with the property that for some $a, b \in R^{+}$(or $a \in R$ ) there is a suitable polynomial $f(x, y)$ with $f(a, b) \geqslant 0$, then $R$ is an $l$-domain if it is unital, or satisfies more general conditions.

In $\S 4$ we summarize the results of $\S \S 2$ and 3 in terms of the lower $l$-radical $\beta(R)$ and strengthen the result of Shyr and Viswanathan. In §5 we show that in an $l$-algebra with the polynomial constraints considered previously, if $a \wedge b=0$, then the $l$-ideals generated by $a b$ and $b a$ are identical. In §6 there are some examples and a remark connecting the general constraints with (3) and (4).

Finally, we fix some notation and give a few more useful facts. If $X$ is a subset of the $l$-ring $R$, then $\langle X\rangle$ will denote the convex $l$-subgroup of $R$ generated by $X$. Also,

$$
M_{2}=\left\{a \in R^{+}: a^{2}=0\right\}
$$

(5) If $R$ is a torsion free $l$-algebra over $F$ and $0<\beta \in F$ and $a \in R$ with $\beta a \geqslant 0$ ( $\beta a \leqslant 0$ ), then $a \geqslant 0(a \leqslant 0)$.
(6) $\left\langle R^{n}\right\rangle=\left\{r \in R:|r| \leqslant s^{n}\right.$ for some $\left.s \in R^{+}\right\}$is an $l$-ideal of $R$.
(7) If $a \wedge b=a \wedge c=0$, then $a \wedge(b+c)=0$.
(8) If $a, b \in R$ and $a_{1}=a-a \wedge b, b_{1}=b-a \wedge b$, then $a_{1} \wedge b_{1}=0$.
(9) If $a^{*} \wedge b^{*}=0$ in a homomorphic image $R^{*}$ of $R$, then there exist $a$ and $b$ in $R$, mapping to $a^{*}$ and $b^{*}$, respectively, and $a \wedge b=0$.
2. Squares positive. Our first lemma is included for ease of reference, and is, for $F=\mathbf{Z}$ (except (d)), Example 15 of $[4$, p. 55]. The next two lemmas determine when an $l$-semiprime $l$-ring is $l$-reduced or reduced.

Lemma 1. Let $R$ be a torsion-free l-algebra over the totally ordered domain $F$, and let

$$
T=\{c \in R:|c| \text { is an f-element of } R\} .
$$

Then:
(a) $T$ is a convex f-subalgebra of $R$.
(b) If $R$ is unital and $1>0$, then $F \subseteq T$.
(c) If $0 \neq \beta \in F$ and $a \in R$ with $\beta a \in T$, then $a \in T$.
(d) $R$ is a T-T f-bimodule.

Proof. We will only prove (c). If $x \wedge y=0$ in $R$, then $|\beta a| x \wedge y=0$ implies

$$
|\beta|(|a| x \wedge y)=|\beta||a| x \wedge|\beta| y=|\beta a| x \wedge|\beta| y=0
$$

So $|a| x \wedge y=0$ since $R$ is $F$-torsion-free; similarly, $x|a| \wedge y=0$, so $a \in T$.
We will consistently denote the $f$-subring of f-elements of $R$ by $T$, or $T(R)$, if necessary.

Lemma 2. Let $R$ be an l-ring. If $a \in R^{+}$is an f-element of $R$ and $a^{2}=0$, then $a R a=0$.

Proof. Let $z \in R^{+}$. Then $(a z-z a)^{+} \wedge(a z-z a)^{-}=0$ and hence $(a z-z a)^{+} a$ $\wedge a(a z-z a)^{-}=0$. Since $(a z-z a)^{+} a=\left(a z a-z a^{2}\right)^{+}=a z a$ and $a(a z-z a)^{-}=$ $\left(a^{2} z-a z a\right)^{-}=a z a$, we have $a z a=a z a \wedge a z a=0$.

Recall that $M_{2}=\left\{a \in R^{+}: a^{2}=0\right\}$ and $N_{2}=\left\{a \in R: a^{2}=0\right\}$.
Lemma 3. Let $R$ be an l-ring.
(a) $R$ is l-reduced if and only if it is l-semiprime and $M_{2} \subseteq T$.
(b) $R$ is reduced if and only if it is l-semiprime and $N_{2} \subseteq T$.
(c) $R$ is an l-domain if and only if it is l-prime and $M_{2} \subseteq T$.
(d) $R$ is a reduced l-domain if and only if it is l-prime and $N_{2} \subseteq T$.

Proof. (a) If $R$ is $l$-semiprime and $M_{2} \subseteq T$, then $M_{2}=0$ by Lemma 2; hence $R$ is $l$-reduced.
(b) Suppose that $R$ is $l$-semiprime and $N_{2} \subseteq T$. If $a \in N_{2}$, then $|a| \in T$ and $|a|^{2}=\left|a^{2}\right|=0$ since $T$ is an $f$-subring. So $|a|=0$ by Lemma 2 , and hence $R$ is reduced.
(c) follows from (a), and (d) follows from (b).

In the following $T^{0}=\left\langle T^{0}\right\rangle$ is defined to be $\mathbf{Z}$ and $u^{0}=1$ (even if $1 \notin R$ ). The next result is a generalization of [14, Lemma 4(b), p. 203].

Lemma 4. Let $R$ be an l-ring with squares positive. Suppose that $a \in R$ and $k, l, m$, $n \in \mathbf{Z}^{+}$with $1 \leqslant l \leqslant m+k+2$. If $\left\langle T^{k}\right\rangle a^{2^{n}}\left\langle T^{m}\right\rangle \subseteq\left\langle T^{l}\right\rangle$, then

$$
\left\langle T^{k}\right\rangle a\left\langle T^{n+m}\right\rangle+\left\langle T^{k+n}\right\rangle a\left\langle T^{m}\right\rangle \subseteq\left\langle T^{l}\right\rangle
$$

Proof. We use induction on $n$. If $n=0$ this is trivial. Suppose it is true for some integer $n$ and $\left\langle T^{k}\right\rangle a^{2^{n+1}}\left\langle T^{m}\right\rangle \subseteq\left\langle T^{l}\right\rangle$. Then $\left\langle T^{k}\right\rangle a^{2}\left\langle T^{n+m}\right\rangle+\left\langle T^{k+n}\right\rangle a^{2}\left\langle T^{m}\right\rangle \subseteq$ $\left\langle T^{\prime}\right\rangle$. If $t \in T^{+}$, then $0 \leqslant(a \pm t)^{2}$ yields $-\left(t^{2}+a^{2}\right) \leqslant t a+a t \leqslant t^{2}+a^{2}$ and
hence $|t a+a t| \leqslant t^{2}+a^{2}$. But $R$ is a $T-T f$-bimodule, and $|a t|,|t a| \leqslant|a t+t a|$ holds in any totally ordered $T-T$ bimodule which is a homomorphic image of $R$, since $t \geqslant 0$; so it also holds in $R$. Now $|a t| \leqslant t^{2}+a^{2}$ implies

$$
\left|t^{k} a t^{n+m+1}\right|=t^{k}|a t| t^{n+m} \leqslant t^{k+n+m+2}+t^{k} a^{2} t^{n+m} \in\left\langle T^{l}\right\rangle
$$

so $t^{k} a t^{n+m+1} \in\left\langle T^{l}\right\rangle$. Thus $\left\langle T^{k}\right\rangle a\left\langle T^{n+m+1}\right\rangle \subseteq\left\langle T^{l}\right\rangle$ by (6), and, similarly, $\left\langle T^{k+n+1}\right\rangle a\left\langle T^{m}\right\rangle \subseteq\left\langle T^{l}\right\rangle$.

The subset $X$ of the $l$-ring $R$ is said to have local bi-f-superunits if for each $x \in X$ there is an element $e \in T^{+}$with $|x| \leqslant|x| e+e|x|+e|x| e$ (that is, $x$ is in the convex $l-T$ - $T$-bimodule of $R$ generated by $T x+x T$ ). The following theorem implies that a unital $l$-prime $l$-ring with squares positive is a domain.

Theorem 1. Let $R$ be an l-ring in which the square of every element is positive.
(a) $R$ is l-reduced (an l-domain) if and only if it is l-semiprime (l-prime) and $M_{2}=\left\{a \in R^{+}: a^{2}=0\right\}$ has local bi-f-superunits.
(b) $R$ is reduced (a domain) if and only if it is l-semiprime (l-prime) and $N_{2}=\left\{a \in R: a^{2}=0\right\}$ has local bi-f-superunits.

Proof. (a) Suppose that $R$ is $l$-semiprime and $M_{2}$ has local bi-f-superunits. If $a \in M_{2}$, then by Lemma 4 , with $k=m=0$ and $n=l=1, a T+T a \subseteq T$, and hence $a T+T a+T a T \subseteq T$. If $U$ is the convex $l$-subgroup of $R$ generated by $a T+T a+T a T$, then $U=\left\{u \in R:|u| \leqslant a t+t a+\right.$ tat for some $\left.t \in T^{+}\right\} \subseteq T$, and $a \in U$ since $a$ has a bi-f-superunit. So $M_{2} \subseteq T$ and $R$ is $l$-reduced by Lemma 3(a). If $R$ is also $l$-prime, then it is an $l$-domain by Lemma 3(c).
(b) If $R$ is $l$-semiprime and $N_{2}$ has local bi- $f$-superunits, then, as in the previous paragraph, $N_{2} \subseteq T$. So $R$ is reduced by Lemma 3(b). If $R$ is also $l$-prime, then it is a reduced $l$-domain. But if $a b=0$, then $a^{2} b^{2}=0$ implies $a^{2}=0$ or $b^{2}=0$, and hence $a=0$ or $b=0$.

Another version of Theorem 1 is implied by the following two lemmas. The left annihilator of a subset $X$ of $R$ is $l_{R}(X)=\{a \in R: a x=0$ for each $x \in X\}$; the right annihilator of $X$ will be denoted by $r_{R}(X)$.

Lemma 5. Let $R$ be an l-ring and suppose that $X \subseteq T$ with $X \subseteq X_{1}-X_{1}$ where $X_{1}=\left(X \cap R^{+}\right) \cup\{0\}$. Then $r_{R}(X)=r_{R}(\langle X\rangle)$ is a right l-ideal of $R$, and $l_{R}(X)=$ $l_{R}(\langle X\rangle)$ is a left l-ideal of $R$.

Proof. Let $x \in X$ and $r \in r_{R}(X)$. Then $x=x_{1}-x_{2}$ where $x_{1}, x_{2} \geqslant 0$ and $x_{1}$, $x_{2} \in X \cup\{0\}$. If $|s| \leqslant|r|$, then

$$
\begin{aligned}
|x s| & =\left|\left(x_{1}-x_{2}\right) s\right| \leqslant\left|x_{1} s\right|+\left|x_{2} s\right| \\
& =x_{1}|s|+x_{2}|s| \leqslant x_{1}|r|+x_{2}|r|=\left|x_{1} r\right|+\left|x_{2} r\right|=0 .
\end{aligned}
$$

So $s \in r_{R}(X)$ and $r_{R}(X)$ is a right $l$-ideal of $R$. Since $X \subseteq\langle X\rangle, r_{R}(\langle X\rangle) \subseteq r_{R}(X)$. Since $\langle X\rangle=\left\{u \in R:|u| \leqslant x_{1}+\cdots+x_{n}\right.$ for some $\left.0 \leqslant x_{i} \in X_{1}\right\}$, if $r \in r_{R}(X)$ and $u \in\langle X\rangle$ with $|u| \leqslant x_{1}+\cdots+x_{n}$, then $|u r| \leqslant|u||r| \leqslant x_{1}|r|+\cdots+x_{n}|r|=0$, since $|r| \in r_{R}(X)$. Thus ur $=0$ and $r \in r_{R}(\langle X\rangle)$. So $r_{R}(X) \subseteq r_{R}(\langle X\rangle)$. Similarly, $l_{R}(X)=l_{R}(\langle X\rangle)$ is a left $l$-ideal of $R$.

Lemma 6. Let $R$ be an l-ring with squares positive and suppose that $a \in R$ with $a^{2^{n}} \in T$. If $u \wedge v=0$ in $R$, then $|a| u \wedge v \in r_{R}\left(T^{n}\right)$ and $u|a| \wedge v \in l_{R}\left(T^{n}\right)$. (If $n=0, r_{R}\left(T^{n}\right)=l_{R}\left(T^{n}\right)=0$.)

Proof. By Lemma 4 with $k=m=0$ and $l=1, a T^{n}+T^{n} a \subseteq T$. If $n=0$ the result is obvious; so assume $n \geqslant 1$. If $0 \leqslant s \in\left\langle T^{n}\right\rangle$, then $s \leqslant t^{n}$ for some $t \in T^{+}$by (6). So $s(|a| u \wedge v) \leqslant t^{n}(|a| u \wedge v)=\left|t^{n} a\right| u \wedge t^{n} v=0$. Since $\left\langle T^{n}\right\rangle=\left\langle T^{n}\right\rangle^{+}$ $-\left\langle T^{n}\right\rangle^{+},|a| u \wedge v \in r_{R}\left(\left\langle T^{n}\right\rangle\right)=r_{R}\left(T^{n}\right)$ by Lemma 5.

Theorem 2. Let $R$ be an l-ring in which the square of every element is positive and suppose that $l_{R}(T)=r_{R}(T)=0$. Then:
(a) $R$ is reduced if and only if it is l-semiprime.
(b) $R$ is a domain if and only if it is l-prime.

Proof. By Lemma 6, $N_{2} \subseteq T$, and hence (a) follows from Lemma 3(b). If $R$ is $l$-prime, then it is a reduced $l$-domain by Lemma 3(d), and hence a domain (see the proof of Theorem 1).
3. Polynomial constraints which generalize squares positive. In this section we show that Theorems 1 and 2 are true for $l$-algebras which satisfy polynomial constraints more general than $x^{2} \geqslant 0$. The types of constraints that we use are illustrated in the next two results which are generalizations of [14, Theorem 7, p. 200].

Let $F$ be a totally ordered domain. A polynomial $f(x, y) \in F[x, y]$ will be called nice if it has at least one monomial of degree 1 in $x$ and each of its monomials of degree 1 in $x$ has a negative coefficient. So if $f(x, y)$ is nice, then $f(x, y)=-g(x, y)$ $+p(y)+h(x, y)$ where $0 \neq g(x, y)$ is of degree 1 in $x$ and all its coefficients are positive, and $h(x, y)=0$ or each of its monomials is of degree at least 2 in $x$. For example, for each $\alpha \in F, f(x, y)=-(x y+y x)+\alpha\left(x^{2}+y^{2}\right)$ is nice; so is $(y-x)^{n}$ and modifications obtained by putting in appropriate coefficients $\alpha \in F$ in the monomials of $(y-x)^{n}$. Note that $y$ need not appear in the nice polynomial $f(x, y)$. We will consistently denote the "parts" of a nice polynomial $f(x, y)$ by $g(x, y), p(y)$ and $h(x, y)$, as in the definition.

The derivative of $p(x) \in F[x]$ will be denoted by $p^{\prime}(x)$. If $f(x, y)$ is a nice polynomial then $f(x, 1)^{\prime}(0)<0$.

Lemma 7. Let $R$ be a unital torsion-free l-algebra over the totally ordered domain $F$. The following statements are equivalent for the nilpotent element a of $R$.
(a) $|a|<1$.
(b) There is a polynomial $p(x)$ in $F\left[x^{2}\right]$ with $p\left(a^{n}+1\right) \geqslant 0$ and $p\left(a^{n}-1\right) \geqslant 0$ for each $n \geqslant 1$, and $0 \neq p^{\prime}(1) \cdot 1 \in R^{+}$.
(c) For each integer $n \geqslant 1$ there are polynomials $p_{1}(x)$ and $q_{1}(x)$ in $F[x]$ with $p_{1}\left(a^{n}+1\right) \geqslant 0, q_{1}\left(\left(a^{n}-1\right)^{2}\right) \geqslant 0$ and $p_{1}^{\prime}(1) q_{1}^{\prime}(1) \cdot 1>0$ in $R$.
(d) For each integer $n \geqslant 1$ there are polynomials $p_{2}(x)$ and $q_{2}(x)$ in $F[x]$ with $p_{2}\left(a^{n}+1\right) \geqslant 0, q_{2}\left(a^{n}-1\right) \geqslant 0$ and $p_{2}^{\prime}(1) q_{2}^{\prime}(-1) \cdot 1<0$ in $R$.
(e) $1 \in R^{+}$and for each $b$ in $\left\{ \pm a^{n}: n \geqslant 1\right\}$ there is a polynomial $f(x, y) \in F[x, y]$ such that $f(b, 1) \geqslant 0$ and $f(x, 1)^{\prime}(0)<0$.
(f) $1 \in R^{+},|a|$ is nilpotent and if $u \wedge v=0$ with $u \leqslant\left|a^{m}\right|$ for some $m \in \mathbf{Z}^{+}$and $v \leqslant 1$, then there is a nice polynomial $f(x, y) \in F[x, y]$ with $f(u, v) \geqslant 0$.
(g) For each integer $n \geqslant 1$ there are polynomials $p_{3}(x)$ and $q_{3}(x) \in F[x]$, with only odd terms, such that $p_{3}(b)^{+} p_{3}(b)^{-}=0$ if $b= \pm\left(a^{n}+1\right)$, and $q_{3}(b)^{+} q_{3}(b)^{-}=0$ if $b= \pm\left(a^{n}-1\right) ;$ and $p_{3}(1) p_{3}^{\prime}(1) q_{3}(1) q_{3}^{\prime}(1) \cdot 1>0$ in $R$.

Proof. For (a) $\rightarrow$ (b) let $p(x)=x^{2}$ and use the fact that $T$ is an $f$-ring (Lemma $1(\mathrm{a})$ ). For (b) $\rightarrow$ (c) let $p_{1}(x)=p(x)$ and $q_{1}(x)=h(x)$ where $p(x)=h\left(x^{2}\right)$ in (b). For $(\mathrm{c}) \rightarrow(\mathrm{d})$ let $q_{2}(x)=q_{1}\left(x^{2}\right)$ and $p_{2}(x)=p_{1}(x)$.
$(\mathrm{d}) \rightarrow(\mathrm{e})$. Let $b=a^{n}$ and take $p_{2}(x), q_{2}(x) \in F[x]$ with $p_{2}\left(a^{n}+1\right) \geqslant 0$, $q_{2}\left(a^{n}-1\right) \geqslant 0$ and $p_{2}^{\prime}(1) q_{2}^{\prime}(-1) \cdot 1<0$. If $\beta=p_{2}^{\prime}(1) q_{2}^{\prime}(-1)>0$, then $1<0$ in $R$ by (5). So $\beta<0,(-\beta) \cdot 1>0$ and $1 \in R^{+}$. Now

$$
\begin{aligned}
0 & \leqslant q_{2}(b-1)=\alpha_{0}+\alpha_{1}(b-1)+\alpha_{2}(b-1)^{2}+\cdots+\alpha_{m}(b-1)^{m} \\
& =\left(\alpha_{1}-2 \alpha_{2}+\cdots+(-1)^{m-1} m \alpha_{m}\right) b+\alpha_{0}+h(b) \\
& =q_{2}^{\prime}(-1) b+\alpha_{0}+h(b)
\end{aligned}
$$

where $h(x) \in x^{2} F[x]$. Similarly, there exists $h_{1}(x) \in x^{2} F[x]$ with

$$
0 \leqslant p_{2}(b+1)=p_{2}^{\prime}(1) b+\gamma_{0}+h_{1}(b)
$$

If $q_{2}^{\prime}(-1)<0$, then $f_{+}(x, y)=q_{2}^{\prime}(-1) x+\alpha_{0}+h(x)$ is a nice polynomial with $f_{+}(b, 1) \geqslant 0$. Also, $p_{2}^{\prime}(1)>0$ since $p_{2}^{\prime}(1) q_{2}^{\prime}(-1)<0$, and $f_{-}(x, y)=-p_{2}^{\prime}(1) x+\gamma_{0}+$ $h_{2}(x)$ is a nice polynomial with $f_{-}(-b, 1) \geqslant 0$; here, if $h_{1}(x)=\sum \gamma_{i} x^{i}$, then $h_{2}(x)=$ $\Sigma(-1)^{i} \gamma_{i} x^{i}$.

If $q_{2}^{\prime}(-1)>0$, then again we get two nice polynomials $f_{ \pm}(x, y)$ with $f_{+}(b, 1) \geqslant 0$ and $f_{-}(-b, 1) \geqslant 0$.
(e) $\rightarrow$ (a). By induction on the index of nilpotency of $a$ we may assume that $a^{k} \in T$ if $k \geqslant 2$. Let $f(x, y)=g(x, y)+p(y)+h(x, y)$ be a polynomial with $f(x, 1)^{\prime}(0)<0$ and $f(a, 1)=g(a, 1)+p(1)+h(a, 1) \geqslant 0$, where the monomials of $g(x, y)$ (respectively, $h(x, y)$ ) are of degree 1 (respectively, 2) in $x$. Then, since $g(a, 1)=-\beta a$ where $\beta=-f(x, 1)^{\prime}(0)>0$ and $h(a, 1) \in a^{2} F[a] \subseteq T$, we have $\beta a \leqslant s$ for some $s \in T$. By using a similar polynomial for $-a$, we get $-\gamma a \leqslant t$ for some $t \in T$ and $0<\gamma \in F$. So $-\beta t \leqslant \gamma \beta a \leqslant \gamma s$ and $a \in T$ by Lemma 1(a) and (c). Since (a) holds in any totally ordered ring, it must hold in any $f$-ring.
(f) $\rightarrow$ (a). By induction on the index of nilpotency of $b=|a|$, we may assume that $b^{n}=0, n \geqslant 2$, and $b^{k} \in T$ if $k \geqslant 2$. Let $c=b \wedge 1$, and let $u=b-c$ and $v=1-c$. Then $c, v \in T$ and $u \wedge v=0$ by (8). Let $f(x, y)=-g(x, y)+p(y)+h(x, y)$ be a nice polynomial with $f(u, v) \geqslant 0$. Then $0 \leqslant g(u, v) \leqslant p(v)+h(u, v)$. Each term of $h(u, v)$ is of the form $\alpha w=\alpha u^{n_{1}} v^{m_{1}} u^{n_{2}} v^{m_{2}} \cdots u^{n_{t}} v^{m_{t}}$ with $N=\Sigma n_{i} \geqslant 2$. Since $v \leqslant 1,0 \leqslant w \leqslant u^{N} \leqslant b^{N} \in T$; so $\alpha w \in T$ and hence $h(u, v) \in T$. Whence $g(u, v) \in$ $T$ since $p(v) \in T$. Now $g(u, v)$ contains a term of the form $\alpha u, \alpha u v^{m}, \alpha v^{m} u$ or $\alpha v^{m} u v^{k}$, where $\alpha>0$ and $m, k \geqslant 0$. Since $g(x, y)$ has positive coefficients, if $d$ is this term, then $0 \leqslant d \leqslant g(u, v)$ and hence $u, u v^{m}, v^{m} u$ or $v^{m} u v^{k} \in T$ (Lemma 1(c)). But $v=1-c$ is an invertible element in $T$ (since $c^{n}=0$ ), hence $u \in T$ and $b=u+c \in T$.
$(\mathrm{g}) \rightarrow(\mathrm{d})$. Since $p_{3}(x)$ has only odd terms $p_{3}(-b)=-p_{3}(b)$; and hence $p_{3}(-b)^{+}=$ $p_{3}(b)^{-}$and $p_{3}(-b)^{-}=p_{3}(b)^{+}$. So if $b=a^{n}+1$, then $p_{3}(b)^{+} p_{3}(b)^{-}=0$ and $p_{3}(b)^{-} p_{3}(b)^{+}=0$, and hence

$$
p_{3}(b)^{2}=\left[p_{3}(b)^{+}-p_{3}(b)^{-}\right]^{2}=\left[p_{3}(b)^{+}\right]^{2}+\left[p_{3}(b)^{-}\right]^{2} \geqslant 0 .
$$

Similarly, $q_{3}(b)^{2} \geqslant 0$ if $b=a^{n}-1$. Let $p_{2}(x)=p_{3}(x)^{2}$ and $q_{2}(x)=q_{3}(x)^{2}$. Then $p_{2}\left(a^{n}+1\right) \geqslant 0, q_{2}\left(a^{n}-1\right) \geqslant 0$ and $p_{2}^{\prime}(1) q_{2}^{\prime}(-1) \cdot 1<0$ in $R$.

Since $T$ is a convex $f$-subring of $R$ (Lemma $1(\mathrm{a})$ ) and hence satisfies (3) and (4), for the implication (a) $\rightarrow$ (f) we may let $f(x, y)=-(x y+y x)+x^{2}+y^{2}$, and for (a) $\rightarrow(\mathrm{g})$ we may let $p_{3}(x)=q_{3}(x)=x$. The proof is complete.

The next lemma shows that polynomials also determine when the idempotents are in $T$.

Lemma 8. The following statements are equivalent for the unital torsion-free l-algebra $R$ over the totally ordered domain $F$.
(a) The idempotents of $R$ are contained in the interval $[0,1]$ (and are central).
(b) There is a polynomial $p(x)$ in $F[x]$ with $p(f) \geqslant 0$ for each idempotent $f$, and [ $p(1)-p(0)] \cdot 1>0$ in $R$.
(c) For each idempotent $f$ there are polynomials $p(x)$ and $q(x)$ in $F[x]$ with $p(f) \geqslant 0, q(1-f) \geqslant 0$ and $[p(1)-p(0)][q(1)-q(0)] \cdot 1>0$ in $R$.
(d) For each idempotent $f$ there are polynomials $p(x)$ and $q(x)$ in $F[x]$, with zero constant terms, such that $p(f)^{+} p(f)^{-}=q(f)^{-} q(f)^{+}=0$ and $p(1) q(1)>0$.

Proof. Since $T$ is an $f$-ring (Lemma $1(\mathrm{a})$ ) squares are positive in $T$ and $T$ satisfies $x^{+} x^{-}=0$; so (a) implies (b) and (d), and clearly (b) implies (c). Also, for (d) implies (a) we can simply note that for $f$ idempotent $p(f)=p(1) f$ and $q(f)=q(1) f$, and so $f^{+} f^{-}=f^{-} f^{+}=0$. Hence $f=f^{2} \geqslant 0$ and $1-f \geqslant 0$. Now we show that $(\mathrm{c}) \rightarrow(\mathrm{a})$.

By (5) $1 \in R^{+}$, since $[p(1)-p(0)][q(1)-q(0)] \cdot 1>0$. Also $0 \leqslant p(f)=p(0)+$ $[p(1)-p(0)] f$ and $0 \leqslant q(1-f)=q(1)-[q(1)-q(0)] f$ yield

$$
-p(0) \leqslant[p(1)-p(0)] f \quad \text { and } \quad[q(1)-q(0)] f \leqslant q(1)
$$

So, as in the proof of (e) $\rightarrow$ (a) of Lemma 7, $f \in T$. But (a) is satisfied in any unital $f$-algebra [7, p. 539]. For if $f=f^{2}$ in a unital totally ordered algebra, then $0 \leqslant f \leqslant 1$ $-f$ or $0 \leqslant 1-f \leqslant f$, and hence $f=0$ or 1 . Thus, a unital $f$-algebra satisfies (a), since it is a subdirect product of totally ordered algebras. Consequently, by Lemma $1(a)$, the idempotents of $R$ are contained in $[0,1]$ and commute, and hence are central.

Note that the conditions on the coefficients of the polynomials are important. For any algebraic $l$-algebra $R$ will satisfy the constraint $p(a) \in R^{+}$, but it need not satisfy (a) of Lemmas 7 and 8.

Results analogous to Theorem 1 follow from Lemmas 7 and 3. We state one such result which uses (d) of Lemma 7.

Theorem 3. Let $R$ be a unital torsion-free l-algebra over the totally ordered domain $F$.
(a) $R$ is l-reduced (an l-domain) with $1 \in R^{+}$if and only if $R$ is l-semiprime (l-prime) and for each element a in $M_{2}=\left\{a \in R^{+}: a^{2}=0\right\}$ there is a polynomial $q_{2}(x)$ in $F[x]$ with $q_{2}(a-1) \geqslant 0$ and $q_{2}^{\prime}(-1) \cdot 1<0$ in $R$.
(b) $R$ is reduced (a reduced l-domain) with $1 \in R^{+}$if and only if $R$ is l-semiprime (l-prime) and for each element a in $N_{2}=\left\{a \in R: a^{2}=0\right\}$ there are polynomials $p_{2}(x)$ and $q_{2}(x)$ in $F[x]$ with $p_{2}(a+1) \geqslant 0, q_{2}(a-1) \geqslant 0$ and $p_{2}^{\prime}(1) q_{2}^{\prime}(-1) \cdot 1<0$ in $R$.

Next, we determine, in terms of polynomial constraints, when a unital $l$-domain is a domain. Let $\bar{F}$ be the totally ordered field of quotients of the totally ordered domain $F$, and let $R$ be a torsion-free $l$-algebra over $F$. Then $\bar{R}=R \otimes_{F} \bar{F}=\{r / \alpha$ : $r \in R$ and $0 \neq \alpha \in F\}$ is the $F$-divisible hull of $R$. If $\bar{R}$ is given the positive cone $\bar{R}^{+}=\left\{r / \alpha: r \in R^{+}\right.$and $\left.\alpha \in F^{+}\right\}$, then $\bar{R}$ is an $l$-algebra over $\bar{F}$ which contains $R$.

The $F$-l-algebra $R$ will be called normal (i-normal) if for each $a$ in $R$ which is a zero divisor there is a polynomial $0 \neq p(x)$ in $F[x]$, with zero constant term, such that $p(a) \geqslant 0$ (and $p(1) \neq 0)$.

Lemma 9. Let $R$ be a unital, reduced, normal l-algebra over the totally ordered domain $F$, and suppose that $R$ is an l-domain. Then the following statements are equivalent.
(a) $R$ is a domain and $1 \in R^{+}$.
(b) If $c^{2}=\alpha c$ with $c \in R$ and $0<\alpha \in F$, then there is a polynomial $p(x)$ in $F[x]$ such that $p(c) \in R^{+}$and $[p(\alpha)-p(0)] \cdot 1>0$ in $R$.
(c) The idempotents of $\bar{R}=R \otimes_{F} \bar{F}$ are positive.
(d) $\bar{R}$ is i-normal over $\bar{F}$ and $1 \in R^{+}$.

Proof. (a) $\rightarrow$ (b). If $c^{2}=\alpha c$ with $\alpha>0$, then $f=c / \alpha$ is an idempotent of $\bar{R}$, and since $\bar{R}$ is a domain, $f=0$ or 1 . So $c=0$ or $\alpha$ and we can let $p(x)=x$.
(b) $\rightarrow$ (c). First note that $1 \in R^{+}$by (5). Let $f=c / \alpha$ be an idempotent in $\bar{R}$ with $\alpha>0$. Then $1-f=(\alpha-c) / \alpha$ is idempotent and $c^{2}=\alpha c$ and $(\alpha-c)^{2}=\alpha(\alpha-c)$. Let $p(x), q(x) \in F[x]$ be such that $p(c) \geqslant 0, q(\alpha-c) \geqslant 0$ and $p(\alpha)-p(0)>0$, $q(\alpha)-q(0)>0$. Then $p(c)=p(\alpha f)=p(0)+[p(\alpha)-p(0)] f \geqslant 0$ and $q(\alpha-c)=$ $q(\alpha(1-f))=q(0)+[q(\alpha)-q(0)](1-f) \geqslant 0$. So $-p(0) \leqslant[p(\alpha)-p(0)] f$ and $[q(\alpha)-q(0)] f \leqslant q(\alpha)$, and hence $f \in T(\bar{R})$ since $F \subseteq T$ by Lemma 1 .
(c) $\rightarrow$ (a). Since $\bar{T}=T \otimes_{F} \bar{F}$ is the set of $f$-elements of the $l$-domain $\bar{R}, \bar{T}$ is an $f$-ring (Lemma 1 (a)) and hence is a domain. But the idempotents of $\bar{R}$, being positive, are contained in $\bar{T}$; and hence 0 and 1 are the only idempotents of $\bar{R}$. Let $a b=0$ in $R$; then, since $R$ is a normal $l$-algebra, there are nonzero polynomials $p(x)$ and $q(x)$ in $x F[x]$ with $p(a) \geqslant 0$ and $q(b) \geqslant 0$. Since $R$ is an $l$-domain and $p(a) q(b)=0$, either $p(a)=0$ or $q(b)=0$; suppose $p(a)=0$ and $a \neq 0$. Then, since $\bar{R}$ is reduced, the algebraic element $a$ is strongly regular in $\bar{F}[a]$; that is, $a=a^{2} h(a)$ for some polynomial $h(x)$ in $\bar{F}[x]$. For, since $\bar{F}[a]$ is reduced, $\bar{F}[a] \simeq$ $\bar{F}[x] /(g(x))$ with $g(x)$ square free; so that $\bar{F}[a]$, as a ring, is a direct sum of fields (or see [8, p. 165]). Since $f=a h(a)$ is an idempotent of $\bar{R}, f=0$ or $f=1$; thus $f=1$ and $b=0$.
(d) $\rightarrow$ (c). Let $f \neq 0,1$ be an idempotent of $\bar{R}$. Since $\bar{R}$ is $i$-normal there exists $p(x) \in x \bar{F}[x]$ with $0 \leqslant p(f)=p(1) f$ and $p(1) \neq 0$. Then $p(1)^{2} f \geqslant 0$ and hence $f \geqslant 0$ by (5).

Since (a) trivially implies (d) the proof is complete.
Note that the equivalence of (b) and (c) in Lemma 9 holds for any unital $l$-algebra. From Theorem 3 and Lemmas 7 and 9 we get the following two corollaries.

Corollary 1. Let $R$ be a unital torsion-free l-algebra over the totally ordered domain $F$. Then $R$ is a domain with $1 \in R^{+}$if and only if it is a normal l-prime l-algebra which satisfies (i) and (ii).
(i) If $a \in R$ with $a^{2}=0$, then there are polynomials $p_{2}(x)$ and $q_{2}(x) \in F[x]$ with $p_{2}(a+1) \geqslant 0, q_{2}(a-1) \geqslant 0$ and $p_{2}^{\prime}(1) q_{2}^{\prime}(-1) \cdot 1<0$ in $R$.
(ii) If $c^{2}=\alpha c$ where $0<\alpha \in F$ and $c \in R$, then there exists $p(x) \in F[x]$ with $p(c) \in R^{+}$and $[p(\alpha)-p(0)]>0$.

The $F$-l-algebra is weakly p-positive if for each $a$ in $R$ there is a polynomial $p(x) \in F[x]$ (of degree $\geqslant 1$ ) with $p(a) \geqslant 0$ and $p^{\prime}(1)>0$ in $F$; it is strongly $p$-positive if for each $a$ in $R, p(x)$ exists with positive coefficients with $p(a) \geqslant 0$.

Corollary 2. Let $R$ be a unital, weakly p-positve, torsion-free l-algebra over the totally ordered domain $F$.
(a) If $1 \in R^{+}$, then $R$ is a reduced l-domain if and only if it is l-prime.
(b) If $F$ is a field and $1 \in R^{+}$, then $R$ is a domain if and only if it is an i-normal l-prime l-algebra.
(c) If $R$ is strongly p-positive, then $1 \in R^{+}$and $R$ is a domain if and only if it is a normal l-prime l-algebra.

Proof. (a) follows from Lemmas 7(c) and 3(d), and then (b) follows from Lemma $9(\mathrm{~d})$. If $R$ is a strongly $p$-positive normal $l$-prime $l$-algebra, then $p(1) \cdot 1 \in R^{+}$with $p(x) \in F^{+}[x]$ implies $1 \in R^{+}$, and hence $F^{+} \subseteq R^{+}$. Thus $R$ is a domain by Corollary 1.

Example 1 in $\S 6$ shows that (b) is false if $F=\mathbf{Z}$, even if $R$ is commutative and the idempotents of $R$ are positive. It also shows that a weakly $p$-positive $l$-algebra need not be strongly $p$-positive. We also note that [16, Example 2] shows that a commutative unital $l$-domain with all idempotents positive, which is a $p$-positive $l$-algebra over a totally ordered field $F$, need not be reduced. In this example each element $a$ satisfies an inequality $(x-\alpha)^{2} \geqslant 0$. In fact, if $R$ is any $l$-algebra with squares positive and $R_{1}=R+F$ is the $l$-algebra obtained from $R$ by freely adjoining $F$ in the usual manner (so $R_{1}^{+}=\left\{(r, \alpha)\right.$ : $r \in R^{+}$and $\left.\alpha \in F^{+}\right\}$), then $R_{1}$ is a $p$-positive $l$-algebra with $1>0$. Each element of $R_{1}$ satisfies $(x-\alpha)^{2} \geqslant 0$ for some $\alpha \in F . R_{1}$ will be an $l$-domain if $R$ is an $l$-domain. Analogous statements are true for any $p$-positive $l$-algebra.

If $A$ is a finite subset of a strongly $p$-positive $l$-algebra $R$, then there is a polynomial $p(x) \in F^{+}[x]$ with $p(a) \geqslant 0$ for each $a$ in $A$. For if $a_{1}$ and $a_{2}$ are in $R$ and if $p_{1}(x), p_{2}(x) \in F^{+}[x]$ with $p_{2}\left(a_{2}\right) \in R^{+}$and $p_{1}\left(p_{2}\left(a_{1}\right)\right) \in R^{+}$, then $p\left(a_{i}\right) \in$ $R^{+}$for $i=1,2$ where $p(x)=p_{1}\left(p_{2}(x)\right)$. Similarly, the direct sum of a family of
strongly $p$-positive $l$-algebras is strongly $p$-positive. Since the direct sum need not be unital, we note that throughout this paper, the condition " $1 \in R^{+}$" may be replaced by " $R$ has central f-units"; that is, for each $a \in R$ there is an idempotent $e$ in $T$ which is central in $R$ and $a=a e$.
We turn next to two-variable polynomials and give the following generalization of Lemma 4.

Lemma 10. Let $R$ be a torsion-free l-algebra over the totally ordered domain $F$. Suppose that $a \in R$ and $1 \leqslant k \in \mathbf{Z}$. Assume that for each $t \in T^{+}$and each integer $m \geqslant 0$ there are two nice polynomials $f_{i}(x, y)=-g_{i}(x, y)+p_{i}(y)+h_{i}(x, y) \in$ $F[x, y], i=1,2$, with $f_{1}\left(a^{k^{m}}, t\right) \geqslant 0, f_{2}\left(-a^{k^{m}}, t\right) \geqslant 0$ and such that:
(i) $g_{1}(x, y)$ or $g_{2}(x, y)$ has a monomial ending in $x$ and $g_{2}\left(a^{k^{m}}, t\right) \leqslant g_{1}\left(a^{k^{m}}, t\right)$.
(ii) $h_{i}(x, y) \in F\left[x^{k}, y\right]$; so $h_{i}(x, y)=q_{i}\left(x^{k}, y\right)$ for $i=1,2$.

If $a^{k^{n}} \in T$ for some $n \geqslant 0$, then for each $s \in T \cup\{1\}$ and for each $t \in T$ there is an integer $N \geqslant 0$ with $t^{N_{s}} \in T$.
Moreover, if the degree in $y$ of each monomial of $g_{i}(x, y)$ which ends in $x($ for all $t \in T^{+}$and $m \geqslant 0$ ) is bounded by $M_{1}$, and the degree of each $q_{i}(x, y)$ in $x$ is bounded by $M_{2}$, then we may take $N \leqslant M_{1}\left(M_{2}^{n}+M_{2}^{n-1}+\cdots+1\right)$.

Proof. Let $t \in T$ and $s \in T \cup\{1\}$. We may assume that $s \geqslant 0$ and $t \geqslant 0$. For if $|t|^{N}|s| a \in T$, then

$$
\left|t^{N_{s}}\right| \leqslant|t|^{N}|s||a|=\left||t|^{N}\right| s|a| \in T
$$

implies that $t^{N_{s}} a \in T$ by Lemma 1. Let $t_{1}=t \vee s$ if $s \neq 1$ and let $t_{1}=t$ if $s=1$. We argue by induction on $n$. If $n=0$, then $a \in T$ and we can let $N=0$. Assume the result is true for the integer $n$ and $a^{k^{n+1}} \in T$, and let $b=a^{k}$. Then $b^{k^{n}} \in T$ and hence for each $s_{1} \in T \cup\{1\}$ there is an integer $N_{1}$ with $t_{1}^{N_{1}} s_{1} b \in T$ (and $N_{1} \leqslant M_{1}\left(M_{2}^{n}+M_{2}^{n-1}+\cdots+1\right)$ if $M_{1}$ and $M_{2}$ exist). Now for each integer $r \geqslant 1$ there is an integer $N_{r}$ with $t_{1}^{N_{r}} s_{1} b^{r} \in T$ (and $N_{r} \leqslant r M_{1}\left(M_{2}^{n}+M_{2}^{n-1}\right.$ $+\cdots+1)$ ). For if $s_{2}=t_{1}^{N} s_{1} b^{r} \in T$, then there exists an integer $M$ with $t_{1}^{M} s_{2} b \in T$ (and $M \leqslant M_{1}\left(M_{2}^{n}+M_{2}^{n-1}+\cdots+1\right)$ ); but $t_{1}^{M} s_{2} b=t_{1}^{M} t_{1}^{N_{r}} s_{1} b^{r+1}$ and hence $N_{r+1}=$ $M+N_{r}\left(\right.$ and $N_{r+1} \leqslant(r+1) M_{1}\left(M_{2}^{n}+M_{2}^{n-1}+\cdots+1\right)$.
Let $f_{1}(x, y)=-g_{1}(x, y)+p_{1}(y)+h_{1}(x, y)$ be a nice polynomial which satisfies (ii) and such that $f_{1}\left(a, t_{1}\right) \geqslant 0$. If $u$ is a term of $h_{1}\left(a, t_{1}\right)=q_{1}\left(a^{k}, t_{1}\right)=q_{1}\left(b, t_{1}\right)$, then

$$
u=\alpha t_{1}^{i_{1}} b^{j_{1}} t_{1}^{i_{2}} b^{j_{2}} \cdots t_{1}^{i_{1}} b^{j_{1}}
$$

with $0 \neq \alpha \in F, l \geqslant 1, i_{1} \geqslant 0, j_{l} \geqslant 0$ and $j_{1} \geqslant 1$. We claim that $t_{1}^{L} u \in T$ for some $L$ (and $L \leqslant\left(\sum_{\nu=1}^{l} j_{\nu}\right) M_{1}\left(M_{2}^{n}+M_{2}^{n-1}+\cdots+1\right)$ ). If $l=1$ this follows from the previous paragraph. Assume that $l \geqslant 2$ and $t_{1}^{L_{1}}\left(\alpha t_{1}^{i_{1}} b^{j_{1}} \cdots t_{1}^{i_{-1}} b^{j_{l-1}}\right)=s_{3} \in T$ (and $L_{1} \leqslant$ $\left.\left(\sum_{\nu=1}^{l-1} j_{\nu}\right) M_{1}\left(M_{2}^{n}+M_{2}^{n-1}+\cdots+1\right)\right)$. Then, again, there is an integer $L_{2}$ with

$$
t_{1}^{L_{1}+L_{2}} u=t_{1}^{L_{2}}\left(s_{3} t_{1}^{i_{1}}\right) b^{j_{l}} \in T
$$

and so

$$
L=L_{1}+L_{2}
$$

(and

$$
\left.L \leqslant\left(\sum_{\nu=1}^{l} j_{\nu}\right) M_{1}\left(M_{2}^{n}+M_{2}^{n-1}+\cdots+1\right) \leqslant M_{1}\left(M_{2}^{n+1}+M_{2}^{n}+\cdots+M_{2}\right)\right)
$$

Thus, there exists $L_{3}$ with $t_{1}^{L_{3}} h_{1}\left(a, t_{1}\right) \in T$ (and $L_{3} \leqslant M_{1}\left(M_{2}^{n+1}+\cdots+M_{2}\right)$ ).
Similarly, if $f_{2}(x, y)=-g_{2}(x, y)+p_{2}(y)+h_{2}(x, y)$ is a nice polynomial which satisfies (i) and (ii) and $f_{2}\left(-a, t_{1}\right) \geqslant 0$, then there is an integer $L_{4}$ with $t_{1}^{L_{4}} h_{2}\left(-a, t_{1}\right)$ $\in T$ (and $L_{4} \leqslant M_{1}\left(M_{2}^{n+1}+M_{2}^{n}+\cdots+M_{2}\right)$ ). Let $L_{5}$ be the larger of $L_{3}$ and $L_{4}$ $\left(L_{5} \leqslant M_{1}\left(M_{2}^{n+1}+M_{2}^{n}+\cdots+M_{2}\right)\right)$. Then $t_{1}^{L_{5}} g_{i}\left(a, t_{1}\right) \in T$. For $g_{1}\left(a, t_{1}\right) \leqslant p_{1}\left(t_{1}\right)$ $+h_{1}\left(a, t_{1}\right)$ and $g_{2}\left(-a, t_{1}\right) \leqslant p_{2}\left(t_{1}\right)+h_{2}\left(-a, t_{1}\right)$. But $g_{2}\left(-a, t_{1}\right)=-g_{2}\left(a, t_{1}\right)$, so

$$
-\left(p_{2}\left(t_{1}\right)+h_{2}\left(-a, t_{1}\right)\right) \leqslant g_{2}\left(a, t_{1}\right) \leqslant g_{1}\left(a, t_{1}\right) \leqslant p_{1}\left(t_{1}\right)+h_{1}\left(a, t_{1}\right)
$$

Thus

$$
\begin{aligned}
-t_{1}^{L_{5}}\left(p_{2}\left(t_{1}\right)+h_{2}\left(-a, t_{1}\right)\right) & \leqslant t_{1}^{L_{s}} g_{2}\left(a, t_{1}\right) \leqslant t_{1}^{L_{5}} g_{1}\left(a, t_{1}\right) \\
& \leqslant t_{1}^{L_{5}}\left(p_{1}\left(t_{1}\right)+h_{1}\left(a, t_{1}\right)\right)
\end{aligned}
$$

and $t_{1}^{L_{s}} g_{i}\left(a, t_{1}\right) \in T$ by Lemma 1(a).
Now suppose $g_{1}\left(a, t_{1}\right)$ has a term of the form $\beta t_{1}^{L_{6}} a$. But $t_{1} \geqslant 0$ and all the coefficients of $g_{1}(x, y)$ are in $F^{+}$, so $\left|\beta t_{1}^{L_{6}} a\right| \leqslant\left|g_{1}\left(a, t_{1}\right)\right|$, since this inequality holds in any totally ordered $F-T-T$ bimodule which is a homomorphic image of $R$, and $R$ is a subdirect product of these modules. Thus $\beta\left|t_{1}^{L_{5}} t_{1}^{L_{6}} a\right| \leqslant t_{1}^{L_{5}}\left|g_{1}\left(a, t_{1}\right)\right|=$ $\left|t_{1}^{5} g_{1}\left(a, t_{1}\right)\right|$, and if $N=L_{5}+L_{6}$ then $t_{1}^{N} a \in T$ by Lemma 1(c) (and

$$
\left.N \leqslant M_{1}\left(M_{2}^{n+1}+M_{2}^{n}+\cdots+M_{2}\right)+M_{1}=M_{1}\left(M_{2}^{n+1}+M_{2}^{n}+\cdots+1\right)\right)
$$

If $N=0$, then $a \in T$ and $t^{N_{s}} s \in T$. If $N \geqslant 1$, then $0 \leqslant t^{N-1} s \leqslant t_{1}^{N}$ and hence $\left|t^{N-1} s a\right|=t^{N-1} s|a| \leqslant t_{1}^{N}|a|=\left|t_{1}^{N} a\right|$; so $t^{N-1} s a \in T$ by Lemma 1(a).

In [7], as part of their characterization of those $f$-rings that can be embedded in unital $f$-rings, Henriksen and Isbell defined an $f$-ring to be infinitesimal if it satisfies the identity $x^{2} \leqslant|x|$ (equivalently $n x^{2} \leqslant|x|$ for each $n \in \mathbf{Z}^{+}$). In [15, Remark, $p$. 367] we have called an $l$-ring which satisfies the "dual" identities $n|x| \leqslant\left|x^{2}\right|$ supertesimal. Since the essential use of the nice polynomials $f(x, y)$ in Lemmas 7 and 10 is that " $x \leqslant$ higher powers of $x$ ", we make the following definitions.

A ( $p$-) pseudosupertesimal l-algebra over $F$ is an $l$-algebra $R$ such that for all $a$, $r \in R$, with $r \geqslant 0$ (and $a \geqslant 0$ ), there is a nice polynomial $f(x, y)=-g(x, y)+p(y)$ $+h(x, y)$ in $F[x, y]$ with $f(a, r) \geqslant 0$. A nice polynomial $f(x, y)$ is called $k$ restricted if $h(x, y) \in F\left[x^{k}, y\right] . R$ is a (right) $k$-restricted pseudosupertesimal l-alge$b r a$ if for all $a, r \in R$ with $r \geqslant 0$ there are two $k$-restricted nice polynomials $f_{1}(x, y)$ and $f_{2}(x, y)$ with $f_{1}(a, r) \geqslant 0, f_{2}(-a, r) \geqslant 0, g_{2}(a, r) \leqslant g_{1}(a, r)$ and $g_{1}(x, y)+$ $g_{2}(x, y)$ has monomials which begin and end in $x\left(g_{1}(x, y)+g_{2}(x, y)\right.$ has a monomial which ends in $x$ ). $R$ is a (right) $p$ - $k$-restricted pseudosupertesimal l-algebra if for all $a, r \in R^{+}$there is a $k$-restricted polynomial $f(x, y)$ with $f(a, r) \geqslant 0$ and $g(x, y)$ has monomials which begin and end with $x$ (which end in $x$ ). Finally, a bounded pseudosupertesimal l-algebra (etc.) is an $l$-algebra $R$ for which there is an integer $K$ such that for all $a, r \in R$ with $r \geqslant 0$ there is a nice polynomial $f(x, y)$ with $f(a, r) \geqslant 0$ and the degree of $y$ in $g(x, y)$ is $\leqslant K$ and the degree of $h(x, y)$ in $x$
is $\leqslant K$. For example, a square archimedean $l$-ring is a bounded $p$-2-restricted pseudosupertesimal $l$-algebra over $\mathbf{Z}$. And a strongly $p$-positive $l$-algebra $R$ is pseudosupertesimal, since if $p(x) \in F^{+}[x]$, then $f(x, y)=p(y-x)$ is a nice polynomial; and if $R$ is unital, then for each element $a$ of $R$ there is a nice polynomial $f(x)=f(x, 1)$ with $f(a) \geqslant 0$; so $R$ is $p$-2-restricted. Also, a commutative $p$-pseudosupertesimal $l$-algebra is $p$-2-restricted. If $R$ is a PPI $l$-algebra with a nice $k$-restricted polynomial $f(x, y)=-g(x, y)+p(y)+h(x, y)$ and $g(x, y)$ has monomials which end in $x$, then $R$ is right $k$-restricted; if $R$ just satisfies $f\left(x^{+}, y^{+}\right)^{-}=0$ then it is right $p-k$-restricted.

We can now give other generalizations of Theorems 1 and 2. The subset $X$ of the $l$-ring $R$ is said to have local (left) $f$-superunits if for each $x \in X$ there is an $e \in T^{+}$ with $|x| \leqslant e|x|$ and $|x| \leqslant|x| e(|x| \leqslant e|x|)$. The element $a \in R$ is regular if $l_{R}(a)=r_{R}(a)=0$.

Theorem 4. Let $R$ be a pseudosupertesimal torsion-free l-algebra over the totally ordered domain $F$, and suppose that $2 \leqslant k \in \mathbf{Z}$.
(a) If $R$ is right p-k-restricted, then $R$ is l-reduced (an l-domain) if and only if it is $l$-semiprime (l-prime) and $M_{2}=\left\{a \in R^{+}: a^{2}=0\right\}$ has local left $f$-superunits.
(b) If $R$ is right $k$-restricted, then $R$ is reduced if and only if it is $l$-semiprime and $N_{2}=\left\{a \in R: a^{2}=0\right\}$ has local left $f$-superunits.

Proof. (a) Suppose that $R$ is $l$-semiprime and $a \in M_{2}$ and $e \in T^{+}$with $a \leqslant e a$. Since $a^{k} \in T$ and $a \geqslant 0$ we may use Lemma 10 with $f_{2}(x, y)=-g_{1}(x, y)$. Then $a \leqslant e^{N} a \in T$; hence $a \in T$ by Lemma l(a) and $R$ is $l$-reduced by Lemma 3(a).

The proof of (b) is similar.
Theorem 5. Let $R$ be a pseudosupertesimal torsion-free l-algebra over the totally ordered domain $F$, and suppose that $k \geqslant 2$. Suppose that $l_{R}(T)=0=r_{R}(T)$ and $R$ is bounded; or $T$ contains a regular element of $R$.
(a) If $R$ is $p$-k-restricted and l-semiprime (l-prime), then it is l-reduced (an $l$-domain).
(b) If $R$ is $k$-restricted and $l$-semiprime, then it is reduced.

Proof. (a) If $a \in M_{2}$ and $t \in T^{+}$, then by Lemma 10 and its right counterpart $t^{N} a$ and $a t^{N}$ are in $T$ for some integer $N$. So if $u \wedge v=0$ in $R$, then $t^{N}(a u \wedge v)=0$ and $(u a \wedge v) t^{N}=0$. If $s \in T$ is regular in $R$, then so is $t=s^{2} \geqslant 0$; so $a \in T$. If $R$ is bounded, then $N$ is independent of $t$ (Lemma 10), so $a u \wedge v \in r_{R}\left(\left\langle T^{N}\right\rangle\right)=r_{R}\left(T^{N}\right)$ by Lemma 5, and $u a \wedge v \in l_{R}\left(T^{N}\right)$. If we also have $l_{R}(T)=r_{R}(T)=0$, then again $a \in T$. Thus by Lemma 3(a) $R$ is $l$-reduced.

The proof of (b) is similar to that of (a).
From Theorem 4 and Lemma 9(d) we get
Corollary 3. Let $R$ be a right $k$-restricted $(k \geqslant 2)$ pseudosupertesimal l-algebra over the totally ordered field $F$, and suppose that $R$ is unital with $1 \in R^{+}$. If $R$ is an l-prime i-normal l-algebra, then $R$ is a domain.
4. The lower $l$-radical. If $\beta(R)$ is the lower $l$-radical of $R$, then since $R / \beta(R)$ is $l$-semiprime, Lemma 3 translates to

Lemma 11. Let $R$ be an l-ring.
(a) $\beta(R)=\{a \in R:|a|$ is nilpotent $\}=M$ if and only if for $0 \leqslant a \in M$ and $u \wedge v=0$ in $R, a u \wedge v \in \beta(R)$ and $u a \wedge v \in \beta(R)$. This is true if $M^{+} \subseteq T$.
(b) $\beta(R)=\{a \in R: a$ is nilpotent $\}=N$ if and only if for $a \in N$ and $u \wedge v=0$ in $R,|a| u \wedge v \in \beta(R)$ and $u|a| \wedge v \in \beta(R)$. This is true if $N \subseteq T$.

Lemmas 4, 7 and 10 (and the conditions in Theorems 4 and 5) offer a variety of polynomial characterizations of when $\beta(R)=M$ or $\beta(R)=N$. We record some of these explicitly (as implications). As usual, $R$ is a torsion-free $l$-algebra over the totally ordered domain $F$.

Theorem 6. Each of the following conditions implies that $\beta(R)=\{a \in R:|a|$ is nilpotent $\}=M \subseteq T$.
(a) $R$ is a right p-k-restricted pseudosupertesimal l-algebra for some integer $k \geqslant 2$ and $R$ has local left $f$-superunits.
(b) $R$ is a p-k-restricted pseudosupertesimal l-algebra, with $l_{R}(T)=r_{R}(T)=0$ and $R$ is bounded; or $T$ contains a regular element of $R(k \geqslant 2)$.
(c) Here, we assume $1 \in R^{+}$. If $u \wedge v=0$ with $u$ nilpotent and $v \leqslant 1$, then there is a nice polynomial $f(x, y) \in F[x, y]$ with $f(u, v) \geqslant 0$.

Proof. By Lemma 11(a) we only need that $M^{+} \subseteq T$. For (a) this follows from the argument in Theorem 4(a), and for (b) it follows from the argument in Theorem 5(a). For (c) use Lemma 7(f).

Theorem 7. Let $R$ be a torsion-free l-algebra over the totally ordered domain $F$. Each of the following conditions implies that $\beta(R)=\{a \in R$ : a is nilpotent $\}=N \subseteq T$.
(a) The square of each element in $R$ is positive; and $R$ has local bi-f-superunits, or $l_{R}(T)=r_{R}(T)=0$.
(b) $R$ is a bounded $k$-restricted pseudosupertesimal l-algebra and $l_{R}(T)=r_{R}(T)=0$ ( $k \geqslant 2$ ).
(c) $R$ is a $k$-restricted pseudosupertesimal l-algebra and $T$ contains a regular element of $R(k \geqslant 2)$.
(d) $1 \in R^{+}$and $R$ is weakly p-positive.

Proof. By Lemma $11(b)$ it suffices to show that each nilpotent element is in $T$. For (a) this follows from Lemmas 4 and 6. For (b) and (c) this follows from Lemma 10 (as in the proof of Theorem 5). For (d) it follows from Lemma 7(c).
Since $\beta(R)$ is an $f$-ring (in Theorems 6 and 7) it is the sum of the nilpotent $l$-ideals of $R$ [5, Theorem 3.1]. Let $Z_{n}=\left\{a \in R:|a|^{n}=0\right\}$ and $N_{n}=\left\{a \in R: a^{n}=0\right\}$. If $M_{2}=\left\{a \in R^{+}: a^{2}=0\right\} \subseteq T$, then $Z_{2}(R)=N_{2}(T)$ is an $l$-ideal of $R$. For if $a \in Z_{2}(R)$, then $|a| \in T$ implies that $a \in T$ since $T$ is a convex $l$-subring. Since $T$ is an $f$-ring (Lemma 1(a)), $\left|a^{2}\right|=|a|^{2}$, and hence $a \in N_{2}(T)$ and $Z_{2}(R)=N_{2}(T)$. By (2), $N_{2}(T)$ is a convex $l$-subgroup of $R$, and then by Lemma $3 Z_{2}(R)=N_{2}(T)$ is an $l$-ideal of $R$. If $M_{2}\left(R / Z_{2}\right) \subseteq T\left(R / Z_{2}\right)$, then $Z_{4}(R)$ is an $l$-ideal of $R$. In particular,
if $R$ satisfies the hypotheses of (a) or (c) of Theorem 6, then each $Z_{2^{n}}$ is a nilpotent $l$-ideal of index at most $2^{n}$, and $\beta(R)$ is the union of $\left\{Z_{2^{n}}\right\}$.

Similarly, if $N_{2} \subseteq T$, then $N_{2}(R)=N_{2}(T)$ is an $l$-ideal of $R$; and if $R$ satisfies the hypotheses of (d) or the first part of (a) of Theorem 7, then each $N_{2^{n}}$ is a nilpotent $l$-ideal of index at most $2^{n}$. and $\beta(R)$ is the union of $\left\{N_{2^{n}}\right\}$.
5. Disjoint elements almost commute. Recall that two elements $a$ and $b$ in an $l$-ring $R$ are called disjoint if $a \wedge b=0$.

It is well known that if $a$ and $b$ are two elements in an $l$-group with $a \wedge b=1$, then $a b=b a[3$, Theorem 6, p. 295]. Trivially, if $a$ and $b$ are disjoint elements of an $l$-ring which satisfies (3), then $a b=b a$. Examples in $\S 6$ show that a unital $l$-ring with squares positive need not have this property. However, Theorem 8 gives the appropriate analogue. We first present two lemmas.

An $l$-ring is $l$-simple if it has exactly two $l$-ideals. A unital totally ordered ring is $l$-simple if and only if whenever $a, b>0$ there exist $c, d \geqslant 0$ with $a \leqslant c b d$. Some examples of commutative unital $l$-simple totally ordered rings $F$ are subrings of the reals, totally ordered fields and (commutative) polynomial rings with coefficients in $F$, ordered appropriately. If $R$ is an $l$-algebra over the totally ordered domain $F$, then an algebra $l$-ideal $I$ is closed if $R / I$ is $F$-torsion-free. For an arbitrary algebra $l$-ideal $I, \hat{I}=\{r \in R: \alpha r \in I$ for some $0 \neq \alpha \in F\}$ is the closure of $I$, and $I$ is closed if and only if $I=\hat{I}$.

Lemma 12. Let $R$ be an l-algebra over the totally ordered domain $F$.
(a) If for each $a \in R^{+}$there exists $e \in R^{+}$with $a \leqslant e a+a e+e a e$, then each l-ideal of $R$ is an algebra l-ideal.
(b) If $F$ is $l$-simple, then each algebra $l$-ideal of $R$ is closed.

Proof. (a) If $I$ is an $l$-ideal of $R, a \in I^{+}$and $\alpha \in F^{+}$, then $\alpha a \leqslant \alpha e a+a \alpha e+\alpha e a e$ implies $\alpha a \in I$.
(b) Let $I$ be an algebra $l$-ideal of $R$. If $0<\alpha \in F$ there exists $\beta \in F^{+}$with $1 \leqslant \beta \alpha$. So if $r \in R$ with $\alpha r \in I$, then $|r| \leqslant \beta \alpha|r|=\beta|\alpha r| \in I$; hence $r \in I$.

Diem stated the next lemma for the case that $R$ has squares positive, but, in fact, proved the more general result given here (a proof is also given in [14, p. 199]). It is the motivation for the somewhat surprising lemma which follows it.

Lemma 13 [5, p. 78]. An l-prime l-ring $R$ is an l-domain if and only if it satisfies the two conditions:
(a) If $a, b \in R^{+}$and $a^{2}=b^{2}=0$, then $a b=0$.
(b) If $a \wedge b=0$ and $a b=0$, then $b a=0$.

The element $a \in R^{+}$is a positive zero-divisor if there is $0 \neq b \in R^{+}$with $a b=0$ or $b a=0$.

Lemma 14. Let $R$ be a torsion-free l-algebra over the totally ordered domain $F$. Suppose that:
(a) If $a \in R^{+}$and $a^{2}=0$, then $a$ is an $f$-element of $R$.
(b) If $u \wedge v=0$, with $u$ a positive zero divisor and $v \in T$, then there exists a polynomial $p(x) \in F^{+}[x]($ of degree $\geqslant 1)$ such that $p(v-u) \geqslant 0$; or there is a nice
polynomial $f(x, y) \in F[x, y]$ with $f(u, v) \geqslant 0$ and $f(x, y)$ has a monomial of degree 1 in $x$ which ends in $x$.

Then if $a, b \in R$ with $a \wedge b=a b=0$, and $e \in T^{+}$, there exists $N \in \mathbf{Z}^{+}$with $e b e^{N} a e=0$.

Proof. We will repeatedly use the fact that $T$ is an $f$-ring (Lemma 1(a)) and hence it satisfies (4).

Let $e \in T^{+}$and let $a_{1}=a \wedge e$ and $b_{1}=b \wedge e$. We first show that $b e^{m} a_{1} e=0$ for each $m \in \mathbf{Z}^{+}$. Let $b_{2}=b-b_{1}$ and $e_{2}=e-b_{1}$; and let $a_{2}=a-a_{1}$ and $f_{2}=e-a_{1}$. Then by (8) we get

$$
\begin{equation*}
b_{2} \wedge e_{2}=0 \tag{10}
\end{equation*}
$$

and

$$
\begin{equation*}
a_{2} \wedge f_{2}=0 \tag{11}
\end{equation*}
$$

Let $b_{0}=b$ and $a_{0}=a$; then since $a_{1} b_{i}=0$ we have

$$
\begin{equation*}
f_{2} b_{i}=e b_{i} \quad \text { for } 0 \leqslant i \leqslant 2 \tag{12}
\end{equation*}
$$

Also, since $a_{i} b_{1}=0$ we get

$$
\begin{equation*}
a_{i} e_{2}=a_{i} e \quad \text { for } 0 \leqslant i \leqslant 2 \tag{13}
\end{equation*}
$$

Now $a_{1} \wedge b_{1} e^{m}=0$ and $a_{1}, b_{1} e^{m} \in T$; so $b_{1} e^{m} a_{1}=0$. Also (10) implies $b_{2} e^{m} a_{1}^{l} \wedge e_{2}$ $=0$, for any $l, m \in \mathbf{Z}^{+}$. But $e_{2} \in T$, and $\left(b_{2} e^{m} a_{1}^{l}\right)^{2}=0$ (if $l \geqslant 1$ ) implies $b_{2} e^{m} a_{1}^{l} \in$ $M_{2} \subseteq T$; so

$$
\begin{equation*}
b_{2} e^{m} a_{1}^{l} e=0 \quad \text { for all } m \in \mathbf{Z}^{+} \text {and } l \geqslant 1 \tag{14}
\end{equation*}
$$

since $b_{2} e^{m} a_{1}^{l} e=b_{2} e^{m} a_{1}^{l} e_{2}=0$, by (13). But then

$$
b e^{m} a_{1} e=\left(b_{2}+b_{1}\right) e^{m} a_{1} e=b_{2} e^{m} a_{1} e+b_{1} e^{m} a_{1} e=0 .
$$

By (11) $b_{1} e^{m} a_{2} \wedge f_{2}=0$, and therefore by (12) $e b_{1} e^{m} a_{2}=f_{2} b_{1} e^{m} a_{2}=0$. So

$$
\begin{equation*}
e b e^{m} a e=e b_{2} e^{m} a_{2} e \quad \text { for all } m \in \mathbf{Z}^{+}, \tag{15}
\end{equation*}
$$

since $e b_{1} e^{m} a_{2}=b e^{m} a_{1} e=0$ and

$$
e b_{2} e^{m} a_{2} e=e\left(b-b_{1}\right) e^{m}\left(a-a_{1}\right) e=e b e^{m} a e-e b e^{m} a_{1} e-e b_{1} e^{m} a_{2} e
$$

Since $\left(b_{2}\left(f_{2} e\right)^{m} a_{2}\right)\left(f_{2} e\right)^{s} \in M_{2} T^{+} \subseteq T^{+}$we get

$$
b_{2}\left(f_{2} e\right)^{m} a_{2}\left(f_{2} e\right)^{s} a_{2} \wedge f_{2}=0
$$

by (11); and hence (12) implies

$$
\begin{equation*}
e b_{2}\left(f_{2} e\right)^{m} a_{2}\left(f_{2} e\right)^{s} a_{2}=0 \quad \text { for all } m, s \in \mathbf{Z}^{+} \tag{16}
\end{equation*}
$$

Let $p(x)$ be a polynomial in $F[x]$ of degree $\geqslant 1$ and with positive coefficients such that $p\left(f_{2} e-a_{2}\right) \geqslant 0$. Then

$$
\begin{equation*}
0 \leqslant \alpha_{0}+\alpha_{1}\left(f_{2} e-a_{2}\right)+\cdots+\alpha_{n}\left(f_{2} e-a_{2}\right)^{n}=p\left(f_{2} e-a_{2}\right) \tag{17}
\end{equation*}
$$

and so ( $\alpha_{0}=0$ if $1 \notin R^{+}$)

$$
\begin{equation*}
0 \leqslant g\left(a_{2}, f_{2} e\right) \leqslant \alpha_{0}+\sum_{k \geqslant 1} \alpha_{k}\left(f_{2} e\right)^{k}+h\left(a_{2}, f_{2} e\right) \tag{18}
\end{equation*}
$$

where $-g\left(a_{2}, f_{2} e\right)$ is the sum of all those monomials in $a_{2}$ and $f_{2} e$ in (17) which contain just one $a_{2}$, and $h\left(a_{2}, f_{2} e\right)$ is the sum of all those monomials which contain more than one $a_{2}$. A typical term in $h\left(a_{2}, f_{2} e\right)$ is of the form $\alpha w=$ $\alpha\left(f_{2} e\right)^{m_{1}} a_{2}\left(f_{2} e\right)^{m_{2}} a_{2} \cdots\left(f_{2} e\right)^{m_{t}}$ with $m_{i} \in \mathbf{Z}^{+}, t \geqslant 3$ and $\alpha \in F$. By (16) $e b_{2} w=0$ and hence $e b_{2} h\left(a_{2}, f_{2} e\right)=0$. From (18) we get
From (18) we get

$$
\begin{equation*}
0 \leqslant e b_{2} g\left(a_{2}, f_{2} e\right) \leqslant \sum \alpha_{k} e b_{2}\left(f_{2} e\right)^{k} \tag{19}
\end{equation*}
$$

A typical term in $g\left(a_{2}, f_{2} e\right)$ is $\alpha\left(f_{2} e\right)^{m} a_{2}\left(f_{2} e\right)^{s}$. But

$$
\begin{equation*}
b_{2}\left(f_{2} e\right)^{m} a_{2}\left(f_{2} e\right)^{s} e \wedge b_{2}=0 \quad \text { for all } m, s \in \mathbf{Z}^{+} \tag{20}
\end{equation*}
$$

since $f_{2} \leqslant e$ and

$$
\begin{aligned}
0 & \leqslant b_{2}\left(f_{2} e\right)^{m} a_{2}\left(f_{2} e\right)^{s} e \wedge b_{2} \leqslant b_{2}\left(f_{2} e\right)^{m} a_{2}\left(e^{2}\right)^{s} e \wedge b_{2} \\
& =b_{2}\left(f_{2} e\right)^{m} a_{2} e_{2} e^{2 s} \wedge b_{2}=0
\end{aligned}
$$

by (13) and (10); and (20) implies

$$
\begin{equation*}
e b_{2}\left(f_{2} e\right)^{m} a_{2}\left(f_{2} e\right)^{s} e \wedge e b_{2}\left(f_{2} e\right)^{k} e=0 \quad \text { for all } m, s, k \in \mathbf{Z}^{+} \tag{21}
\end{equation*}
$$

Now (19), (21) and (7) imply that

$$
0 \leqslant e b_{2} g\left(a_{2}, f_{2} e\right) e=e b_{2} g\left(a_{2}, f_{2} e\right) e \wedge \sum \alpha_{k} e b_{2}\left(f_{2} e\right)^{k} e=0
$$

and hence

$$
\begin{equation*}
e b_{2} g\left(a_{2}, f_{2} e\right) e=0 \tag{22}
\end{equation*}
$$

However, one term in $g\left(a_{2}, f_{2} e\right)$ is $\alpha\left(f_{2} e\right)^{m} a_{2}$ with $0<\alpha \in F$ and $m \geqslant 0$; since $g(x, y) \in F^{+}[x, y]$, (22) implies

$$
\begin{equation*}
e b_{2}\left(f_{2} e\right)^{m} a_{2} e=0 \tag{23}
\end{equation*}
$$

Now for any $k \in \mathbf{Z}^{+}$

$$
\begin{equation*}
b_{2}\left(f_{2} e\right)^{k} a_{2}=b_{2}\left(e-a_{1}\right) e\left(e-a_{1}\right) e \cdots\left(e-a_{1}\right) e a_{2}=b_{2} e^{2 k} a_{2} \tag{24}
\end{equation*}
$$

since all other terms contain a factor $b_{2} e^{r} a_{1}^{l} e$ with $l \geqslant 1$, and $b_{2} e^{r} a_{1}^{l} e=0$ by (14). Thus

$$
\begin{equation*}
e b e^{2 m} a e=e b_{2} e^{2 m} a_{2} e=e b_{2}\left(f_{2} e\right)^{m} a_{2} e=0 \tag{25}
\end{equation*}
$$

by (15), (24) and (23).
If there is a nice polynomial $f(x, y)=-g(x, y)+p(y)+h(x, y)$ with $f\left(a_{2}, f_{2} e\right)$ $\geqslant 0$, then we again get (18) (some $\alpha_{k}$ may be negative); and if $g(x, y)$ has a monomial which ends in $x$, the calculation from (18) through (25) is still valid.

Corollary 4. Suppose that $R$ satisfies the hypotheses of Lemma 14, and it has local left (right) $f$-superunits and $l_{T}(T)=0\left(r_{T}(T)=0\right)$. Then $a \wedge b=a b=0$ implies $b a=0$.

Proof. If $e \in T^{+}$is a left superunit for $\{a, b\}$, then by Lemma $140 \leqslant b a e \leqslant$ $e b e^{N} a e=0$ for some $N$. If $t \in T^{+}$, then $e+t$ is also a left superunit for $\{a, b\}$; so $b a(e+t)=0$ and hence $b a t=0$. Since $l_{T}(T)=0, b a=0$.

The $F$-l-algebra $R$ is called (right) weakly p-pseudosupertesimal if whenever $u \wedge v$ $=0$ in $R$ there exists a nice polynomial $f(x, y)=-g(x, y)+p(y)+h(x, y) \in$ $F[x, y]$ (such that $g(x, y)$ has a monomial ending in $x$ ) and $f(u, v) \geqslant 0$. Note that this is a one variable constraint since $u=a^{+}$and $v=a^{-}$for $a=u-v$.
Theorem 8. Let $R$ be a torsion-free l-algebra over the totally ordered domain $F$, and suppose that $R$ has local f-superunits. Each of the following statements implies that the closed l-ideals of $R$ generated by $a b$ and ba are identical whenever $a \wedge b=0$ in $R$.
(a) $R$ has square positive.
(b) $R$ is unital and strongly p-positive.
(c) $R$ is unital and right weakly p-pseudosupertesimal.
(d) $R$ is right $p$ - $k$-restricted pseudosupertesimal with $k \geqslant 2$.

Proof. We first note that the hypotheses are satisfied by each homomorphic image $R^{*}$ of $R$ (for (c) use (9)). Let $I$ be the $l$-ideal of $R$ generated by $a b ; I$ is an algebra $l$-ideal by Lemma 12(a), with closure $\hat{I}$. If $R^{*}=R / \hat{I}$, then, in each case, we have seen that $M_{2}^{*}=M_{2}\left(R^{*}\right) \subseteq T^{*}=T\left(R^{*}\right)$. For (a) use Lemma 4; for (b) use Lemma 7(d) (or the fact that (b) implies (c)); for (c) use Lemma 7(f); for (d) use Lemma 10. Since $a^{*} \wedge b^{*}=a^{*} b^{*}=0, b^{*} a^{*}=0$ by Corollary 4. So $b a \in \hat{I}$, and similarly, $a b$ is in the closed $l$-ideal of $R$ generated by $b a$.
It is possible to strengthen Theorem 8(b) by assuming weakly $p$-positive and the following. Let $p(x)=p_{1}(x)-p_{2}(x)$ where $p_{1}(x)$ (respectively, $-p_{2}(x)$ ) is the sum of the terms of $p(x)$ with a positive (respectively, negative) coefficient. Then for each $a \in R$ we require $p(x)=p_{1}(x)-p_{2}(x) \in F[x]$ with $p(a) \geqslant 0, p(1)-p(0)>0$ in $R$, and for each $i \geqslant 0, \gamma_{i}=\sum_{k \geqslant i+1}\left(\alpha_{k}-\beta_{k}\right) \geqslant 0\left(\alpha_{k}\right.$ and $\beta_{k}$ are the coefficients of $x^{k}$ in $p_{1}(x)$ and $p_{2}(x)$ ). Now the proof of Lemma 14 goes through with $e=1$. For $b_{2} f_{2}=b_{2}\left(1-a_{1}\right)=b_{2}$ by (14), and hence in (19) $b_{2} g\left(a_{2}, f_{2}\right)=\sum_{i \geqslant 0} \gamma_{i} b_{2} a_{2} f_{2}^{i}$; so the argument after (19) is still valid.
6. Examples and a remark. Let $R$ be a torsion-free $l$-algebra over the totally ordered domain $F$. In [14, Theorem 8] it is shown that the following statements are equivalent if $R$ has a left $f$-superunit $e$ :
(i) $R$ satisfies $x^{+} x^{-}=0$.
(ii) If $a \wedge e=0$, then $a=0$.
(iii) If $a \geqslant 0$ and $a \wedge e$ is nilpotent, then $a \in T$.
(iv) If $a \geqslant 0$ and $(a \wedge e)^{2}=0$, then $a \in T$.
(v) $R$ has squares positive and
(26) If $a \in R^{+}$and $(a \wedge e)^{2}=0$, then $a^{2}=0$.
(vi) Assume $e=1 . R$ is a PPI $l$-algebra with a polynomial $p(x)$ which satisfies (26).

In fact, it is easily seen that (iv) is equivalent to
(vii) $M_{2}=\left\{a \in R^{+}: a^{2}=0\right\} \subseteq T$ and $R$ satisfies (26).

Thus, to get other equivalences, each of the polynomial constraints which generalize squares positive or $x^{+} x^{-}=0$ and implies $M_{2} \subseteq T$ can be substituted for "squares positive" in (v). Hence, these constraints are not that far removed from their squares positive origin.

Example 1. A commutative, unital, reduced, $i$-normal, weakly $p$-positive $l$-domain in which all the idempotents are positive, but which is not a domain (see [4, Example 9f (II), p. 48]).

Let $\bar{R}=\mathbf{Q} \oplus \mathbf{Q}$ be the (ring) direct sum of two copies of the rationals with positive cone $\bar{R}^{+}=\{(u, v): 0 \leqslant v \leqslant u\}$ and let

$$
R=\{(2 n, 2 m)+(k, k): n, m, k \in \mathbf{Z}\} .
$$

Then $\bar{R}$ is an $l$-domain and if $a=(u, v) \in \bar{R}$, then either $p(a) \geqslant 0$ or $p(a) \leqslant 0$, where $p(x)=v x-x^{2}$; so $R$ is an $i$-normal $p$-positive $l$-algebra over $\mathbf{Z}$.
The following table shows that $R$ is weakly $p$-positive.
Table 1

$$
\begin{aligned}
& \quad \frac{a=(u, v) \in \mathbf{Z} \times \mathbf{Z}}{a \in \bar{R}^{+} \cup-\bar{R}^{+} \cup\{(u, 1): u<0\}} \\
& u<0 \text { and } v \geqslant 2 \\
& u<0 \text { and } v<u \\
& u=0 \text { and } v<2 \\
& u=0 \text { and } v=2 \\
& u=0 \text { and } v>2 \\
& u>0 \text { and } v<0 \\
& u>0 \text { and } v>u
\end{aligned}
$$

$$
\begin{gathered}
p(x) \text { with } p(a) \in \bar{R}^{+} \text {and } p^{\prime}(1)>0 \\
p(x)=x^{2} \\
p(x)=v x^{2}-x^{3} \\
p(x)=-v x^{2}+x^{3} \\
p(x)=x^{2}-v x \\
p(x)=2 x+x^{2}-x^{3} \\
p(x)=v x-x^{2} \\
p(x)=x^{2}-v x \\
p(x)=v^{3} x-x^{4}
\end{gathered}
$$

Example 2. A unital l-ring with squares positive in which disjoint elements do not commute.

An example is given by the free algebra generated by the set $X$. Let $\Delta$ be the free semigroup (with identity $e$ ) generated by $X$, and let $Y$ be the set $X$ together with a total order. If $s=x_{1} x_{2} \cdots x_{p} \in \Delta$, then $s$ is said to have length $p: l(s)=p$. We make $\Delta$ into a partially ordered semigroup by defining, for $s, t \in \Delta, s<t$ if
(i) $l \leqslant l(s)<l(t)$ or
(ii) $s=x_{1} \cdots x_{m} x_{m+1} \cdots x_{p}, t=x_{1} \cdots x_{m} y_{m+1} \cdots y_{p}, p \geqslant 2$, and $x_{m+1}<y_{m+1}$ in $Y$ for some $m \geqslant 0$.

In this ordering the set $X \cup\{e\}$ is trivially ordered and is at the "bottom" of $\Delta$, whereas the elements of length $\geqslant 2$ form a chain above $X$. Let $R=A[\Delta]=\{f=$ $\left.\Sigma a_{s} s: s \in \Delta, a_{s} \in A\right\}$ be the semigroup ring of $\Delta$ over the totally ordered domain $A$. By the support of an element $f=\Sigma a_{s} s$ in $R$ we mean $\left\{s \in \Delta: a_{s} \neq 0\right\}$. If $R$ is given the positive cone $R^{+}=\left\{f=\Sigma a_{s} s: a_{s}>0\right.$ if $s$ is a maximal element in the support of $f\}$, then $R$ is a unital $l$-ring with squares positive (this may be verified directly or it follows from [16, Theorem $\mathrm{I}(\mathrm{b})$ and Lemma 2]). If $X$ has at least two elements and if $x$ and $y$ are distinct in $X$, then $x \wedge y=0$ in $R$, but $x y \neq y x$. Another such example is obtained by strengthening the order of $\Delta$ slightly by adding
(iii) $e<t$ if $l(t) \geqslant 2$.

We also note that, if in (i) and (iii) we stipulate that $l(t) \geqslant 2 n$, and if we require that $p \geqslant 2 n$ in (ii), for a fixed positive integer $n$, then $R$ will satisfy $\left(x^{2 n}\right)^{-}=0$ but not $\left(x^{m}\right)^{-}=0$ for $m<2 n$.

The referee has supplied the following simpler example (any example must take into account [15, Theorem 1] and the equivalence of (i) and (ii) in the first paragraph of this section).

Example 3. Let $\theta$ be a nontrivial order preserving automorphism of the totally ordered field $F$. Let $F[x ; \theta]$ be the twisted polynomial ring determined by $\theta$. So the elements of $F[x ; \theta]$ are polynomials $p(x)=a_{0}+a_{1} x+\cdots+a_{n} x^{n}$ where $a_{i} \in F$. The elements of $F[x ; \theta]$ are added as usual and multiplied like polynomials subject to the commutation rule $x a=(a \theta) x$ for any $a \in F$. Let $p(x)>0$ if $n \geqslant 2$ and $a_{n}>0$, and let $a_{0}+a_{1} x \geqslant 0$ if $a_{0} \geqslant 0$ and $a_{1} \geqslant 0$. Then squares in $F[x ; \theta]$ are positive; $a \wedge x=0$ for any $a \in F$, and $a x \neq x a$ if $a \theta \neq a$.
