# THE DERIVED FUNCTORS OF THE PRIMITIVES <br> FOR $B P_{*}\left(\Omega S^{2 n+1}\right)$ <br> BY <br> MARTIN BENDERSKY ${ }^{1}$ 

#### Abstract

Formulas for the Hopf invariant, and the $P$ map in the Novikov double suspension sequence are derived. The formulas allow an effective inductive computation of the $E_{2}$-term of the unstable Adams-Novikov spectral sequence. The 3 primary $E_{2}$-term through the 54 stem is displayed.

1. Introduction. The unstable Adams-Novikov spectral sequence for a (simply connected) space $X$ is a sequence of groups $E_{r}(X), r=2,3, \ldots$, which converge to the homotopy groups of $X$. It is often convenient to localize at a prime $p$ in which case the spectral sequence converges to the homotopy groups of $X$ localized at $p$, and the $E_{2}$-term depends on the Brown-Peterson homology of $X$. If the (ordinary) homology of $X$ is $p$-torsion free, the $E_{2}$-term is Ext in a nonabelian category. If, in addition, the cohomology of $X$ is a free algebra the $E_{2}$-term may be simplified to an Ext in an abelian category [6,7].
An important feature of this spectral sequence is the presence of EHP and double suspension long exact sequences on the $E_{2}$ level [8]. There are two single suspension sequences

$$
\begin{aligned}
& \rightarrow E_{2}^{s}\left(\hat{S}^{2 n}\right) \xrightarrow{\sigma} E_{2}^{s}\left(S^{2 n+1}\right) \xrightarrow{H^{\prime}} E_{2}^{s}\left(S^{2 p n+1}\right) \xrightarrow{P} E_{2}^{s+1}\left(\hat{S}^{2 n}\right) \rightarrow, \\
& \rightarrow E_{2}^{s}\left(S^{2 n-1}\right) \xrightarrow{\sigma} E_{2}^{s}\left(\hat{S}^{2 n}\right) \xrightarrow{H} E_{2}^{s-1}\left(S^{2 p n-1}\right) \rightarrow E_{2}^{s+1}\left(S^{2 n-1}\right) \rightarrow
\end{aligned}
$$

and a double suspension sequence

$$
\cdots \rightarrow E_{2}^{s}\left(S^{2 n-1}\right) \xrightarrow{\sigma^{2}} E_{2}^{s}\left(S^{2 n+1}\right) \xrightarrow{H_{2}} \operatorname{Ext}_{\mathscr{A}}^{s-1}(W(n)) \xrightarrow{P_{2}} E_{2}^{s+1}\left(S^{2 n-1}\right) \rightarrow \cdots
$$

( $\hat{S}^{2 n}$ and $W(n)$ are defined in [8] and $\S 4$.)
All three sequences are derived in [8] by homological methods in a nonabelian category. As a consequence it is difficult to compute the maps in the above sequences or the coaction on $W(n)$.

In this paper we study the double suspension sequence. In §4 we compute the first derived functor of the primitives of $B P_{*}\left(\Omega S^{2 n+1}\right)$ in the category of $B P_{*}(B P)$ coalgebras. This determines the coaction of $W(n)$. In §5 we use a form of the

[^0]composite functor spectral sequence for $B P_{*}\left(\Omega S^{2 n+1}\right)$ in order to describe $H_{2}$ and $P_{2}$. Consequently we obtain information about the single suspension sequences as there are commutative diagrams relating them to the double suspension sequence. With these results the double suspension sequence becomes an inductive method for computing the $E_{2}$ for an odd sphere. A table of the resulting computation appears in the appendix. Further applications will appear.

Throughout this paper a prime $p$ is fixed, and $B P_{*}(X)$ is the (reduced) $B P$ homology of $X$ at the prime $p$. In any category under consideration $I$ stands for the identity functor. The ring of integers is denoted by $Z$, the rationals by $Q$ and the integers localized at $p$ by $Z_{(p)}$.
2. Derived functors. We recall some of the definitions in [7]. A cotriple $(F, \delta, \varepsilon)$ on a category $\mathcal{C}$ is a functor $F: \mathcal{C} \rightarrow \mathcal{C}$ together with natural transformations $\delta: F \rightarrow F^{2}$, $\varepsilon: F \rightarrow I$ such that the following diagrams commute.

An $F$-coalgebra is an object $Y$ of $\mathcal{C}$ together with a map $\psi: Y \rightarrow F Y$ such that the following diagrams commute

A map of $F$-coalgebras $f:\left(Y^{\prime}, \psi^{\prime}\right) \rightarrow(Y, \psi)$ is a map $f: Y^{\prime} \rightarrow Y$ such that $\psi \circ f=F f \circ \psi^{\prime}$. Let $\mathcal{C}(F)$ denote the category of $F$-coalgebras. When the category $\mathcal{C}$ is understood we denote $\mathcal{C}(F)$ by $\mathscr{F}$. The definition of a cotriple guarantees $F Y \in \mathscr{F}$ for $Y \in \mathcal{C}$. With structure map $\delta_{Y}$.

A triple $(H, \mu, \eta)$ on a category $\mathscr{F}$ consists of a functor $H: \mathscr{F} \rightarrow \mathscr{F}$ together with natural transformations $\mu: H^{2} \rightarrow H, \eta: I \rightarrow H$ such that the following diagrams commute.

Let $(F, \delta, \varepsilon)$ be a cotriple on $\mathcal{C}$. The adjoint of the cotriple $(F, \delta, \varepsilon)$ is a triple $\left(H_{F}, \mu_{F}, \eta_{F}\right)$ on $\mathscr{F}(=\mathcal{C}(F))$ defined by $H_{F} Y=F Y$ for $Y \in \mathscr{F}, \mu_{F}=F \varepsilon, \eta_{F}=\psi_{Y}$.

As in [7] a cotriple $F$ determines a functor $\mathbf{H}_{\boldsymbol{F}}$ from $\mathscr{F}$ to the category of cosimplicial complexes over $\mathscr{F}$. Explicitly

$$
\begin{gathered}
\mathbf{H}_{F}(Y)^{n}=H^{n+1}(Y), \quad d^{i}=H^{i} \eta H^{n-i}: H^{n} \rightarrow H^{n+1} \\
s^{i}=H^{i} \mu H^{n-i}: H^{n+2} \rightarrow H^{n+1}
\end{gathered}
$$

where $(H, \mu, \eta)=\left(H_{F}, \mu_{F}, \eta_{F}\right)$.
$\mathbf{H}_{F}$ with the augmentation omitted will be denoted $\tilde{\mathbf{H}}_{F}$. A cosimplicial group ( $K^{n}, d_{n}^{i}, s_{n}^{i}$ ) is acyclic if the homotopy of the chain complex ( $\left.K^{n}, \Sigma_{i}(-1)^{i} d_{n}^{i}\right)$ is zero.

Let $\mathfrak{N} \subset \mathscr{F}$ be the full subcategory of objects of the form $F(C)$ with $C \in \mathcal{C}$. Let $\mathbb{Q}$ be an abelian category.

Given a functor $T: \mathscr{A} \rightarrow \mathcal{Q}, \operatorname{ch} T \tilde{\mathbf{H}}_{F}(Y)$ is the cochain complex with

$$
\left(\operatorname{ch} T \tilde{\mathbf{H}}_{F}(Y)\right)^{n}=T \mathbf{H}_{F}(Y)^{n}, \quad n \geqslant 0, \quad \text { and } \quad \delta=\Sigma(-1)^{i} T d^{i}
$$

If $F$ is a cotriple on $\mathcal{C}$ the $F$-derived functors of $T$ are defined by

$$
R_{\mathscr{F}}^{q} T(Y)=H^{q}\left(\operatorname{ch} T \tilde{\mathbf{H}}_{F}(Y)\right)
$$

In the situation when the functor $\operatorname{Hom}_{\mathscr{F}}(A,-)$ is an abelian group we use the customary notation of Ext for the derived functors of $\operatorname{Hom}_{\mathscr{F}}(A,-)$.
3. Unstable $B P$. We begin by reviewing the necessary facts about $B P$ (see [2] and [7]). Fix a prime $p$. There is an associative ring-spectrum $B P$ with homology algebra $H_{*}(B P ; Z)=Z_{(p)}\left[m_{1}, m_{2}, \ldots\right]$ for canonical generators $m_{n},\left|m_{n}\right|=2\left(p^{n}-1\right)$. Let $A=\pi_{*}(B P), \Gamma=\pi_{*}(B P \wedge B P)$. Then $(A, \Gamma)$ is a "Hopf algebroid", i.e. there are structure maps consisting of a product $\phi: \Gamma \otimes_{A} \Gamma \rightarrow \Gamma$, left, and right unit maps $\eta_{L}$, $\eta_{R}: A \rightarrow \Gamma$, a counit map $\varepsilon: \Gamma \rightarrow A$, and a diagonal $\psi: \Gamma \rightarrow \Gamma \otimes_{A} \Gamma$. The notation $M \otimes_{A} N$ requires that $M$ be a right $A$-module, and that $N$ be a left $A$-module. $\Gamma$ is a right $A$-module by $\eta_{R}$ and a left $A$-module by $\eta_{L}[1]$.

The Hurewicz homomorphism $A \rightarrow H_{*}(B P ; Z)$ is a monomorphism and a rational isomorphism. We consider $m_{n}$ as being in $A \otimes Q$, and let log be the formal power series in $A \llbracket X \rrbracket \otimes Q$ defined by

$$
\log X=\sum_{i \geqslant 0} m_{i} X^{p^{i}}
$$

Let exp be the formal power series inverse to $\log$ characterized by $\exp \log X=X$. The formal group law for $B P$ is given by the formal power series in $A \llbracket X, Y \rrbracket$,

$$
F(X, Y)=\sum a_{i, j} X^{i} Y^{j}=\exp (\log X+\log Y)
$$

where the coefficient $a_{i, j}$ belongs to $A_{2 i+2 j-2}$.
Elements $z_{i}$ from $\Gamma$ may be substituted for the indeterminates and we write $\Sigma^{F} z_{i}$ for $F\left(z_{1}, F\left(z_{2}, \ldots\right)\right.$ ).

There is a canonical anti-isomorphism $c: \Gamma \rightarrow \Gamma$ which satisfies $c \eta_{L}=\eta_{R}$ and $c \eta_{R}=\eta_{L}$. This gives a formal group law $F^{*}$ conjugate to $F$ defined by the formula

$$
\Sigma^{F^{*}} z_{i}=c\left(\Sigma^{F} c\left(z_{i}\right)\right)
$$

Let $v_{i} \in A_{2\left(p^{i}-1\right)}$ be the element defined by Araki [3].

$$
p m_{n}=\sum_{0 \leqslant i \leqslant n} m_{i}\left(v_{n-i}\right)^{p^{i}} ; \quad v_{0}=p .
$$

Let $h_{i} \in \Gamma_{2\left(p^{i}-1\right)}$ be defined by $h_{i}=c t_{i}$ where $\left\{t_{i}\right\}$ are the generators defined in [2]. The

$$
A=Z_{(p)}\left[v_{1}, v_{2}, \ldots\right], \quad \Gamma=A\left[h_{1}, h_{2}, \ldots\right] .
$$

The right action of $A$ on $\Gamma$ is related to the left action of $A$ on $\Gamma$ by the integral form of Ravenel's Formula [13]

$$
\begin{equation*}
\sum^{F^{*}} h_{j}^{p^{i}} \cdot v_{i}=\sum^{F^{*}} v_{j}^{p^{i}} \cdot h_{i} \tag{3.1}
\end{equation*}
$$

$\psi$ is determined by

$$
\begin{equation*}
\Sigma^{F^{*}} \psi\left(h_{i}\right)=\sum^{F^{*}} h_{k}^{p_{j}^{j}} \otimes h_{j} . \tag{3.2}
\end{equation*}
$$

For each finite sequence of nonnegative integers $I=\left(i_{1}, i_{2}, \ldots, i_{n}\right)$ let $h^{I}=h_{1}^{i_{1}} h_{2}^{i_{2}}$ $\cdots h_{n}^{i_{n}}$. The length of $I$ is the integer $l(I)=i_{1}+i_{2}+\cdots+i_{n}$.

Definition 3.3. For each nonnegatively graded free left $A$-module $M$ let $U(M)$ $(V(M))$ be the sub- $A$-module of $\Gamma \otimes_{A} M$ spanned by all elements of the form $h^{I} \otimes_{A}$ $m$ where $2 l(I)<$ degree $m(2 l(I) \leqslant$ degree $m)$.
For an arbitrary left $A$-module $M$ let $F_{1} \xrightarrow{f} F_{0} \rightarrow M \rightarrow 0$ be exact, with $F_{0}$ and $F_{1}$ free. Then define $U(M)=\operatorname{Coker} U(f)(V(M)=\operatorname{Coker} V(f))$.

The definitions of $U(M)$ and $V(M)$ are independent of $F_{1}, F_{0}$ and $f$.
Remark 3.4. The natural maps from $U(M)$ or $V(M)$ to $\Gamma \otimes_{A} M$ are not injective if $M$ has $p$-torsion. For example if $M$ is the free $A \otimes(Z / p Z)$ module on a generator $\iota$ of dimension 3, then $p h_{1}^{2} \otimes_{\iota}$ is nonzero and is in the kernel of the map $U(M) \rightarrow \Gamma \otimes_{A} M$.

There is a $\Gamma$-comodule structure on $\Gamma \otimes_{A} M$ by the map $\psi \otimes 1: \Gamma \otimes_{A} M \rightarrow \Gamma \otimes_{A}$ $\Gamma \otimes_{A} M$. From (3.2) it follows that $\psi \otimes 1$ takes $U(M)$ to $U^{2}(M)$ and $V(M)$ to $V^{2}(M)$, inducing maps

$$
\delta^{U}: U(M) \rightarrow U^{2}(M), \quad \delta^{V}: V(M) \rightarrow V^{2}(M)
$$

There are also counit maps $\varepsilon^{U}: U(M) \rightarrow M$ and $\varepsilon^{V}: V(M) \rightarrow M$ induced by the counit map in $\Gamma$. $\left(U, \delta^{U}, \varepsilon^{U}\right)$ and $\left(V, \delta^{V}, \varepsilon^{V}\right)$ are cotriples on the category of nonnegatively graded left $A$-modules and, by $\S 2$, define categories $\mathscr{U}$ and $\mathfrak{V}$. By construction $\mathscr{U}$ and $\mathscr{V}$ are abelian categories.

Since $\Gamma_{2 n+1}=0$ there are isomorphisms

$$
U(A(2 n)) \simeq U(A(2 n-1)) \simeq V(A(2 n-1)), \quad U(A(2 n+1)) \simeq V(A(2 n))
$$

where $A(m)$ is a free $A$-module on a generator of dimension $m$ (with trivial coaction). Hence for $M$ a free $A$-module the basis of [7,§8] provides a basis of $V(M)$.

Definition $3.5 x \in V(M)$ desuspends if it is in the image of the map. $\sigma$ : $U(M) \rightarrow V(M)$.

Let $C(M)=\operatorname{Coker}(\sigma)$. Then $C(M)$ is free over $A \otimes Z / p Z$ if $M$ is $A$-free [7, p. 245]. Some information about $p$ torsion in $C(M)$ is provided by the following.

Proposition 3.6. $h_{k}^{n} \otimes \iota_{2 n}$ has order $p^{k}$ in $C(A(2 n))$.
Proof. Let $B P_{n}$ be the $2 n$th space in the $\Omega$-spectrum for $B P$. Then by [15] $H_{*}\left(B P_{n} ; Z_{(p)}\right)$ is a bipolynomial Hopf algebra with indecomposables isomorphic to $V(A(2 n))$ and primitives isomorphic to $U(A(2 n))$. By [14] $H_{*}\left(B P_{n} ; Z_{(p)}\right)$ admits a decomposition

$$
\begin{equation*}
H_{*}\left(B P_{n} ; Z_{(p)}\right) \simeq \bigotimes_{i} B_{(p)}\left[x_{i}, d_{i}\right] \tag{*}
\end{equation*}
$$

where $B_{(p)}\left[x_{i}, d_{i}\right]$ is the universal bipolynomial Hopf algebra constructed in [10]. The lowest-dimensional term in $H_{*}\left(B P_{n} ; Z_{(p)}\right)$ is $\iota_{2 n} \in H_{2 n}\left(B P_{n} ; Z_{(p)}\right)$ (denoted $b_{1}^{\circ n}$ in [15]). Hence there is a factor $B_{(p)}[\iota, 2 n]$ in (*). It follows from $[10,(6.1)]$ that there is an element of order $p^{k}$ in $C(A(2 n))_{2 p^{k} n}$.

Using (3.1) we inductively show that $p^{r} h_{r}^{n} \otimes \iota_{2 n}=0$ in $C(A(2 n))$. It suffices to show that $p^{r} h_{r} \otimes \iota_{2}=0$ in $C(A(2))$.

For $r=1$ we have the relation $p h_{1} \otimes \iota_{2}=v_{1} \otimes \iota_{2}-1 \otimes v_{1} \iota_{2}$, which is zero in $C(A(2))$.

We examine the terms in dimension $2\left(p^{r}-1\right)$ in relation (3.1):

$$
\sum_{i, j \leqslant r} F^{F^{*}} h_{j}^{p^{i}} \cdot v_{i}=\sum_{i, j \leqslant r} F^{*} v_{j}^{p^{i}} h_{i} \quad\left(v_{0}=p\right)
$$

Multiplying both sides by $p^{r-1}$ and using the inductive hypothesis we obtain

$$
p^{r-1} h_{r} \cdot p \otimes \iota_{2}=p^{r-1} \cdot p^{p^{r}} h_{r} \otimes \iota_{2} \quad \text { in } C(A(2))
$$

or

$$
p^{r}\left(1-p^{p^{r}-1}\right) h_{r} \otimes \iota_{2}=0 \quad \text { in } C(A(2))
$$

completing the induction.
For dimension reasons it follows that the only element in dimension $2 p^{k} n$ which can have order $p^{k}$ in $C(A(2 n))$ is $h_{k}^{n} \otimes \iota_{2 n}$, proving (3.6).

Remark 3.7. The indecomposable functor applied to (*) gives
Indecomposables $\left(H_{*}\left(B P_{2 n} ; Z_{(p)}\right)\right) \simeq \underset{i}{\bigoplus}\left(\operatorname{Indecomposables} B_{(p)}\left[x_{i}, d_{i}\right]\right)$.
The components are invariant under the Verschiebung [15], so [10, (6.1)] determines $C(A(2 n))$ completely.

Referring to the basis in $[7, \S 8]$ we have the following.
Corollary 3.8. $\left\{p^{k-1} h_{k}^{n} \otimes \iota_{2 n} \mid k=1,2, \ldots\right\} \subset C(A(2 n))$ is a set of elements independent over $A \otimes(Z / p Z)$.

Proof. Let $U^{\prime}(2 n)=P H_{*}\left(B P_{2 n} ; Z_{(p)}\right), V^{\prime}(2 n)=Q H_{*}\left(B P_{2 n} ; Z_{(p)}\right)$, and $C^{\prime}(2 n)$ $=\operatorname{Coker}\left(U^{\prime} \rightarrow V^{\prime}\right)$. Then from (3.6) the elements $\left\{p^{k-1} h_{k}^{n} \otimes \iota_{2 n} \mid k=1,2, \ldots\right\} \subset$ $C^{\prime}(2 n)$ are nonzero elements in different degrees of $C^{\prime}(2 n) \otimes Z / p Z$. Filter $U$ and $V$ by powers of the ideal ( $v_{1}, v_{2}, \ldots$ ), and let $E_{0} U, E_{0} V, E_{0} C$ denote the graded groups associated to the filtration. Then $E_{0} U \simeq A \otimes U^{\prime}, E_{0} V \simeq A \otimes V^{\prime}$ and $E_{0} C \simeq A \otimes C^{\prime}$. Therefore the elements $h_{1}^{n} \otimes \iota, p h_{2}^{n} \otimes \iota, \ldots$ are linearly independent over $A \otimes(Z / p Z)$ in $E_{0} C$ and, therefore, also in $C$.

A cotriple $G$ on the category of ( -1 )-connected free $A$-modules is constructed in [ $7, \S 6$ ]. The associated category $\mathcal{G}$ is the category of unstable $\Gamma$-coalgebras with coalgebra structure defined in [7,(6.10)]. Finally there is the cotriple $S$ defined on the category of positively graded free $A$-modules. $S$ is the free commutative coalgebra functor. The category $\mathcal{S}$ is the same as the category of free $A$ coalgebras (without unit). For a coalgebra with diagonal map $\Delta: M \rightarrow M \otimes_{A} M$ the submodule of primitives is defined by

$$
P(M)=\operatorname{ker}\left(\Delta: M \rightarrow M \otimes_{A} M\right)
$$

As $P G(M) \simeq U(M)$ as a coalgebra [7], the $G$-derived functors of $P$ lie in $\mathfrak{Q}$. For $M=A(n), G(M)$ is isomorphic to $S U(M)$ as coalgebras [7, (7.8)]. If $M \simeq \oplus A\left(n_{i}\right)$,

$$
G(M) \simeq \otimes G\left(A\left(n_{i}\right)\right) \simeq \otimes S U\left(A\left(n_{i}\right)\right) \simeq S U\left(\bigoplus U\left(A\left(n_{i}\right)\right) \simeq S U(M)\right)
$$

where the first isomorphism follows from the definition of $G[7,(6.7)]$. Hence we have

$$
\begin{equation*}
R_{\delta}^{i} P j C \simeq R_{\mathcal{G}}^{i} P C \tag{3.9}
\end{equation*}
$$

as $A$-modules for $C \in \mathcal{G}$, and $j: \mathcal{G} \rightarrow \delta$ the forgetful functor.
The derived functors of $\operatorname{Hom}_{\mathscr{F}}(A,-)(\mathscr{F}=\mathcal{G}, \mathscr{Q}, \mathfrak{V})$ will be abbreviated $\operatorname{Ext}(-)$. For $W \in \mathscr{Q}, \operatorname{Ext}_{\text {Q }}(W)$ may be computed by the cobar complex $\left\{C^{s}(W), d\right\}$ defined in [7, §9].

The following isomorphisms relating the various Ext groups to the unstable Adams-Novikov spectral sequence are proven in [7].

$$
\begin{equation*}
\operatorname{Ext}_{\text {ユ }}(A(2 n+1)) \simeq E_{2}\left(S^{2 n+1}\right) \tag{3.10}
\end{equation*}
$$

and

$$
\operatorname{Ext}_{\S}\left(B P_{*}(X)\right) \simeq E_{2}(X)
$$

when $B P_{*}(X)$ is $A$-free.
4. Derived functors of the primitives. Our objective is to compute $R_{g}^{i} P B P_{*}\left(\Omega S^{2 n+1}\right)$ (which we will abbreviate $R_{g}^{i} P$ in the sequel). The $A$-module structure has been determined in [8, (3.3)].

$$
R_{\S}^{i} P B P_{*}\left(\Omega S^{2 n+1}\right)= \begin{cases}A(2 n) & \text { for } i=0  \tag{4.1}\\ W(n) & \text { for } i=1 \\ 0 & \text { for } i>1\end{cases}
$$

where $A(2 n)$ is the free $A$-module on a generator $\iota_{2 n}$ of dimension $2 n$, and $W(n)$ is a free $A \otimes Z / p Z$ module on generators $\left\{y_{i} \mid i>0\right\}$ with $\left|y_{i}\right|=2 p^{i} n$.

Consider the augmented $\mathcal{G}$-cosimplicial complex constructed in $[8, \S 6]$ :

$$
\begin{equation*}
0 \rightarrow B P_{*}\left(\Omega S^{2 n+1}\right) \rightarrow G(A(2 n)) \Rightarrow G(V(A(2 n))) \cdots \tag{4.2}
\end{equation*}
$$

In [8,(6.1)] (4.2) is proven to be acyclic. As (4.2) is a cosimplicial resolution of $B P_{*}\left(\Omega S^{2 n+1}\right)$ by $G$-models, a standard double complex argument shows that (4.2) may be used to compute $R_{9}^{i} P$. Explicitly $R_{g}^{i} P$ is the homology of the complex.

$$
\mathbf{K}: U(A(2 n)) \xrightarrow{\delta_{0}} U(V(A(2 n))) \xrightarrow{\delta_{1}} U\left(V^{2}(A(2 n))\right) \rightarrow \cdots
$$

where $\delta_{*}$ is the restriction of the differential in the stable cobar resolution of $A(2 n)$ to $U\left(V^{*}(A(2 n))\right.$ ).

Proposition 4.3. Let $y_{k} \in U V A(2 n)$ be defined by

$$
y_{k}=p^{k-1}\left(\psi\left(h_{k}^{n}\right)-h_{k}^{n} \otimes 1\right) \otimes \iota_{2 n} .
$$

Then

$$
R_{g}^{1} P(A(2 n)) \simeq(A \otimes Z / p Z)\left\{y_{1}, y_{2}, \ldots\right\}
$$

Proof. Let $\boldsymbol{H}$ be the complex with $\mathbb{H}^{n}=V^{n+1}(A(2 n))$ with differentials as in $\S 2$. $\boldsymbol{H}$ is acyclic in dimensions $>0$ being the (unaugmented) $\boldsymbol{\nu}$-cobar resolution of $A(2 n)$.

The inclusion $U(A(2 n)) \rightarrow V(A(2 n))$ induces a short exact sequence

$$
0 \rightarrow \mathbf{K} \xrightarrow{i} \mathbb{H} \xrightarrow{j} \mathbb{H} / \mathbb{K} \rightarrow 0 .
$$

It follows that $\partial: H^{i-1}(\mathbb{H} / K) \rightarrow R_{\mathcal{G}}^{i} P$ is an isomorphism for $i>0$. $(\partial$ is the boundary homomorphism of the induced long exact sequence.)

The differential $\delta_{0}: \mathbb{H}^{0} \rightarrow \mathbb{H}^{1}$ is given by $\delta_{0}(z)=(\psi(z)-z \otimes 1) \otimes \iota_{2 n}$. From the definition of $\partial$ it follows that

$$
\partial(x)=i^{-1}(\psi(\bar{x})-\bar{x} \otimes 1) \otimes \iota_{2 n}
$$

for $x$ a cycle in $\mathbb{H} / \mathbf{K}$ and $\bar{x}$ a lift to $\mathbb{H}$.
We shall show that $\left\{p^{k-1} h_{k}^{n} \otimes \iota_{2 n}\right\}$ is a set of cycles in $\mathbb{H} / \mathbb{K}$ and therefore represent elements in $H^{0}(\mathbb{H} / \mathbf{K})$ in dimensions $2 n p^{k}, k=1,2, \ldots$ By (3.8) these elements are independent over $A \otimes(Z / p Z)$. From (4.1) $H^{0}(\mathbb{H} / \mathbb{K}) \cong R_{9}^{1} P \cong W(n)$. So $\left\{p^{k-1} h_{k}^{n} \otimes \iota_{2 n}\right\}$ generate $H^{0}(\mathbb{H} / \mathbb{K})$, and $y_{k}\left(=\partial\left(p^{k-1} h_{k}^{n} \otimes \iota_{2 n}\right)\right)$ generate $R_{9}^{1} P(A(2 n))$.

To see that $p^{k-1} h_{k}^{n} \otimes \iota_{2 n} \in \mathbb{H}$ projects to a cycle in $\mathbb{H} / \mathbb{K}$ we note that $\psi\left(h_{k}\right)=1$ $\otimes h_{k}+h_{k} \otimes 1+\Sigma \gamma_{i}^{\prime} \otimes \gamma_{i}^{\prime \prime}, \gamma_{i}^{\prime}, \gamma_{i}^{\prime \prime} \in B P_{*}\left[h_{1}, h_{2}, \ldots, h_{k-1}\right] \subset \Gamma$. As a consequence in the product

$$
\psi\left(h_{k}^{n}\right)=\psi\left(h_{k}\right)^{n}=1 \otimes h_{k}^{n}+h_{k}^{n} \otimes 1+\sum \alpha_{i}^{\prime} \otimes \alpha_{i}^{\prime \prime}
$$

each term $\alpha_{i}^{\prime}$ has a factor $h_{t}$ with $t \leqslant k-1$. From (3.6) $p^{k-1} h_{t}$, and therefore $\alpha_{i}^{\prime}$ desuspends. Hence $j \delta_{0}\left(p^{k-1} h_{k}^{n} \otimes \iota_{2 n}\right)=0$.

In order to compute the $U$ structure on $R_{9}^{1} P$ we need a more detailed description of $y_{k}$.
From (4.1) $H^{1}(\mathbb{K}) \cong H^{1}(\mathbb{K} \otimes Z / p Z)$. As observed in the proof of (4.3) the factor $h_{t}(t \leqslant k-1)$ in the presence of $p^{k-1}$ produce a desuspension of $\alpha_{i}^{\prime}$. In a similar way a factor of $h_{t}$ with $t<k-1$ in the presence of $p^{k-2}$ will produce a desuspension of $\alpha_{i}^{\prime}$. The remaining factor of $p$ will then kill $\alpha_{i}^{\prime}$ in $\mathbb{K} \otimes Z / p Z$. So the only terms in (3.2) which can contribute a nonzero term to $j^{-1} \delta_{0}\left(p^{k-1} h_{k}^{n} \otimes \iota_{2 n}\right) \otimes Z / p Z$ are those in the formal sum

$$
h_{k-1}^{p} \otimes h_{1}+{F_{F}}^{*} h_{k} \otimes 1+_{F^{*}} h_{k-1} \otimes 1=h_{k-1}^{p} \otimes h_{1}+h_{k} \otimes 1
$$

in dimension $2 p^{k}-2$. So we have in $\mathbb{K} \otimes Z / p Z$,

$$
\begin{equation*}
y_{k}=p^{k-1}\left(\left(h_{k} \otimes 1+h_{k-1}^{p} \otimes h_{1}\right)^{n}-h_{k}^{n} \otimes 1\right) \otimes \iota_{2 n} . \tag{4.4}
\end{equation*}
$$

By definition the $U$ structure on $y_{k}$ is given by applying $\psi$ to the left factors in (4.4). So we have the following formula for the $U$ structure on $W(n)$ :
(4.5) $\quad \psi\left(y_{k}\right)=p^{k-1}\left(\left(\psi\left(h_{k}\right) \otimes 1+\psi\left(h_{k-1}\right)^{p} \otimes h_{1}\right)^{n}-\psi\left(h_{k}\right)^{n} \otimes 1\right) \otimes \iota_{2 n}$
in $U(U V(A(2 n)) \otimes Z / p Z)$. In order to express this in terms of $y_{1}, y_{2}, \ldots$ we first compute the coefficient of $y_{1}$.

Lemma 4.6. $\psi\left(y_{k}\right)=p^{k-1} h_{k-1}^{p} \otimes y_{1} \bmod y_{2}, y_{3}, \ldots$
Proof. Let $\varepsilon: \Gamma \rightarrow A$ be the counit (see §3). The map $\varepsilon \otimes$ id restricts to a map

$$
\varepsilon^{\prime}: U V(A(2 n)) \otimes Z / p Z \rightarrow V(A(2 n)) \otimes Z / p Z
$$

We have from (4.4):

$$
\varepsilon^{\prime}\left(y_{k}\right)= \begin{cases}h_{1}^{n} \otimes \iota_{2 n} & \text { if } k=1  \tag{4.7}\\ 0 & \text { if } k>1\end{cases}
$$

Since $\operatorname{Im}\left(\delta_{0}\right) \subset U(U(A(2 n)))$, where $\delta_{0}$ is the differential in $\mathbb{K}$, we must have

$$
\begin{aligned}
& -1 \otimes y_{k}+\psi\left(y_{k}\right) \\
& \quad=\sum_{i \geq 1} \gamma_{i} \otimes y_{i} \in U(U V(A(2 n)) \otimes Z / p Z) \bmod U(U U(A(2 n)) \otimes Z / p Z)
\end{aligned}
$$

From (4.5) and (4.7) we have
$\gamma_{1} \otimes h_{1}^{n} \otimes \iota_{2 n}=U\left(\varepsilon^{\prime}\right)\left(\psi\left(y_{k}\right)\right)=p^{k-1} h_{k-1}^{p} \otimes h_{1}^{n} \otimes \iota_{2 n} \bmod U U(A(2 n)) \otimes Z / p Z$ and (4.6) follows.

We can now describe $W(n)$ as an unstable $\Gamma$-comodule.
Theorem 4.8. $\psi\left(y_{k}\right)=\sum p^{k-i} h_{k-i}^{n i} \otimes y_{i}$.
Proof. Let $d$ be the differential in the stable cobar complex for $W(n)$ [7].

$$
-d\left(y_{k}\right)=\psi\left(y_{k}\right)-1 \otimes y_{k} .
$$

By (4.6) this is equal to

$$
p^{k-1} h_{k-1}^{p n} \otimes y_{1}+\sum_{i=2}^{k-1} \gamma_{i} \otimes y_{i} \quad\left(\gamma_{i} \in \Gamma\right)
$$

By (4.6) again the coefficient of $y_{1}$ in $d^{2}\left(y_{k}\right)$ is

$$
\sum \gamma_{i} \otimes p^{i-1} h_{i-1}^{p n}-p^{k-1} d\left(h_{k-1}^{p n}\right) .
$$

The only terms in (3.2) which can make a nonzero contribution to $p^{k-1} d\left(h_{k-1}^{p}\right)$ are in the sum $\Sigma_{a+b=k-1} h_{a}^{p^{b}} \otimes h_{b}$. In the product

$$
\begin{aligned}
p^{k-1}\left(\sum_{a+b=k-1} h_{a}^{p^{b}} \otimes h_{b}\right)^{p n} \otimes y_{1}= & p^{k-1} \sum_{a+b=k-1} h_{a}^{n p^{b+1}} \otimes h_{b}^{p n} \otimes y_{1} \\
& +p^{k-1}(\text { mixed terms }) \otimes y_{1}
\end{aligned}
$$

a dimension argument shows that

$$
p^{k-1}(\text { mixed terms }) \otimes y_{1}=0 \bmod p
$$

As $d^{2}\left(y_{k}\right)=0$,

$$
\sum \gamma_{j} \otimes p^{j-1} h_{j-1}^{p n}=\sum p^{k-1} h_{k-j}^{n p_{j}^{j}} \otimes h_{j-1}^{p n}
$$

and (4.8) follows.
5. The double suspension sequence. Let $D^{* *}$ be the double complex defined as follows:

$$
\begin{align*}
& D^{i, j}=U^{i} V^{j}(A(2 n)), \quad i>0, j \geqslant 0,  \tag{5.1}\\
& \partial^{H}: D^{i, j} \rightarrow D^{i, j+1}, \quad \partial^{V}: D^{i, j} \rightarrow D^{i+1, j},
\end{align*}
$$

where $\partial^{H}$ is $(-1)^{i} U^{i-1} \delta\left(\delta\right.$ is the differential in the complex $\mathbb{K}$ of $\S 4$ ), and $\partial^{V}$ is the coboundary in the unstable cobar complex for $U V^{j}(A(2 n))$.

By first taking vertical, then horizontal, homology we obtain $\operatorname{Ext}_{\substack{ }}(2(2 n))$ $\left(\simeq \operatorname{Ext}_{\text {थ }}(A(2 n+1))\right)$ concentrated in filtration zero. By taking homologies in the opposite order we obtain a spectral sequence

$$
\operatorname{Ext}_{\mathscr{U}}\left(R_{9}^{i} P B P_{*}\left(\Omega S^{2 n+1}\right)\right) \Rightarrow \operatorname{Ext}_{\mathscr{\text { U }}}(A(2 n+1)) .
$$

After identification, this is equivalent to the $B P$-double suspension sequence

$$
\begin{align*}
& \cdots \xrightarrow{P_{2}} E_{2}^{s, t-1}\left(S^{2 n-1}\right) \xrightarrow{\sigma^{2}} E_{2}^{s, t+1}\left(S^{2 n+1}\right) \xrightarrow{H_{2}} \operatorname{Ext}_{\mathscr{U}}^{s-1, t-1}(W(n))  \tag{5.2}\\
& \xrightarrow[\rightarrow]{P_{2}} E_{2}^{s+1, t-1}\left(S^{2 n-1}\right) \rightarrow \cdots
\end{align*}
$$

where $\sigma^{2}$ is the double suspension, and $H_{2}$ is the double suspension Hopf invariant. (5.2) is easily seen to be equivalent to the double suspension sequence in [8]. However (5.1) is constructed from additive functors, and does not involve the functor $G$. This enables us to describe the maps in (5.2).

Proposition 5.3. (i) Let $z \in \operatorname{Ext}_{{ }_{2}}(W(n))$ be represented in the unstable cobar complex by $\Sigma \gamma_{k} \otimes y_{k}, \gamma_{k} \in C^{s}(W(n))$. Then

$$
P_{2}(z)=(-1)^{s} \sum \gamma_{k} \otimes d\left(p^{k-1} h_{k}^{n}\right) \otimes \iota_{2 n-1}+\sum d\left(\gamma_{k}\right) \otimes p^{k-1} h_{k}^{n} \otimes \iota_{2 n-1}
$$

where $d$ is the differential in the stable cobar complex.
(ii) Let $x \in E_{2}^{s}\left(S^{2 n+1}\right)$. Then $x$ is represented in the unstable cobar complex by a cycle of the form

$$
\sum \gamma_{k} \otimes p^{k-1} h_{k}^{n} \otimes \iota_{2 n+1}, \quad \gamma_{k} \in C^{*}\left(A\left(2 p^{k} n-1\right) \otimes Z / p Z\right)
$$

modulo terms which desuspend.
(iii) $H_{2}(x)=\Sigma \gamma_{k} \otimes y_{k}$.

Proof. This is a consequence of a standard diagram chase and the description of $W(n)$ in $\S 4$.

Let $\hat{S}^{2 n}$ be a space with $H^{*}\left(\hat{S}^{2 n}\right) \simeq Z\left[\iota_{2 n}\right] /\left(\iota^{P}\right)[8, \S 1]$.

Proposition 5.4. There is a commutative diagram

$$
\begin{array}{ccccccccl}
\rightarrow & E_{2}^{s, t-1}\left(S^{2 n-1}\right) & \xrightarrow[\rightarrow]{\sigma} & E_{2}^{s, t}\left(\hat{S}^{2 n}\right) & \xrightarrow{H} & E_{2}^{s-1, t-1}\left(S^{2 p n-1}\right) & \xrightarrow{P} & E_{2}^{s+1, t}\left(S^{2 n-1}\right) & \rightarrow \\
\| & & \downarrow \sigma & & \downarrow r & & \| \\
\rightarrow & E_{2}^{s, t-1}\left(S^{2 n-1}\right) & \xrightarrow{\sigma^{2}} & E_{2}^{s, t+1}\left(S^{2 n+1}\right) & \xrightarrow{H_{2}} & \text { Exta }_{\|}^{s-1, t}(W(n)) & \xrightarrow{P_{2}} & E_{2}^{s+1, t}\left(S^{2 n-1}\right)
\end{array}
$$

where the top row is exact, $\sigma$ is the suspension, and $r$ is the composite

$$
\begin{aligned}
E_{2}\left(S^{2 p n-1}\right) & \simeq \operatorname{Ext}_{\mathscr{U}}(A(2 p n-1)) \simeq \operatorname{Ext}_{\mathscr{A}}(A(2 p n)) \\
& \rightarrow \operatorname{Ext}_{\mathscr{\sim}}(A(2 p n) \otimes Z / p Z) \rightarrow \operatorname{Ext}_{\mathcal{L}}(W(n))
\end{aligned}
$$

Proof. Let $\hat{S}^{2 n} \rightarrow \Omega S^{2 n+1}$ be the inclusion. By naturality there is an induced map of composite functor spectral sequences [7] and, therefore, of the equivalent long exact sequences. The only point which has to be checked is the fact that the map induces the asserted maps of derived functors. This follows from the map induced on the injective extension sequences used to compute the derived functors. See [8] for details.

Corollary 5.5. (i) $P: E_{2}\left(S^{2 p n-1}\right) \rightarrow E_{2}\left(S^{2 n-1}\right)$ is given by

$$
P(\gamma \otimes \iota)= \pm \gamma \otimes d\left(h_{1}^{n}\right) \otimes \iota_{2 n-1}
$$

i.e. $P$ is composition with the $(\bmod p)$ Whitehead product.
(ii) Let $x \in E_{2}\left(S^{2 n+1}\right)$. $x$ desuspends to $E_{2}\left(\hat{S}^{2 n}\right)$ if and only if $x$ can be represented in the unstable cobar complex by $\gamma \otimes h_{1}^{n} \otimes \iota_{2 n+1}\left(\gamma \in C^{*}(A(2 p n-1))\right)$ modulo terms which desuspend to $E_{1}\left(S^{2 n-1}\right)$.
(iii) Let $x^{\prime} \in E_{2}\left(\hat{S}^{2 n}\right)$ be a desuspension of $x$. Then, in the notation of (ii),

$$
H\left(x^{\prime}\right)=\gamma \otimes \iota_{2 p n-1} \quad(\bmod p) .
$$

It follows that $P$ commutes with the differentials in the unstable Adams-Novikov spectral sequence (see [6, (4.9)]).

Remark 5.6. To see that $H$ commutes with the differentials in the unstable Adams-Novikov spectral sequence we consider the spectral sequence for $\Omega \hat{S}^{2 n}$.

There is an isomorphism

$$
E_{2}\left(\Omega \hat{S}^{2 n}\right) \simeq E_{2}\left(S^{2 n-1}\right) \oplus E_{2}\left(\Omega S^{2 p n-1}\right)
$$

with a nontrivial $d_{2}$,

$$
d_{2}: E_{2}^{s, t}\left(\Omega S^{2 p n-1}\right) \rightarrow E_{2}^{s+2, t+1}\left(S^{2 n-1}\right)
$$

determined by

$$
d_{2}\left(x_{2 p n-2}\right)=d\left(h_{1}^{n}\right) \otimes \iota_{2 n-1}
$$

where $x_{2 p n-2}$ generates $B P_{2 p n-2}\left(\Omega S^{2 p n-1}\right), \iota_{2 n-1}$ generates $B P_{2 n-1}\left(S^{2 n-1}\right)$ and

$$
d\left(h_{1}^{n}\right)=\sum\binom{n}{i} h_{1}^{i} \otimes h_{1}^{n-i} .
$$

$d_{2}$ is the " $P$-map" in the EHP sequence induced in $E_{3}$.

$$
\begin{array}{ccccc}
\stackrel{d_{2}}{\rightarrow} & E_{2}\left(S^{2 n-1}\right) & \rightarrow & E_{3}\left(\Omega \hat{S}^{2 n}\right) & \xrightarrow{h} \\
\text { R } & E_{2}\left(\Omega S^{2 p n-1}\right) & \xrightarrow{d_{2}} \\
& \nearrow & & R & R \\
& E_{3}\left(S^{2 n-1}\right) & & & \\
E_{3}\left(S^{2 p n-1}\right)
\end{array}
$$

where the top row is the consequence of the definition of $E_{3}$ as the homology of $\left(E_{2}, d_{2}\right)$, and $h$ is induced by a map of spaces and therefore commutes with differentials.

For a space $X$ the natural map $B P(\Omega X) \rightarrow \Omega B P(X)$ induces a map of spectral sequences

$$
\omega_{X}: E_{r}^{*, *-1}(\Omega X) \rightarrow E_{r}^{*, *}(X)
$$

$\mathrm{By}[8,(6.1)] \omega_{S^{2 n-1}}$ is an isomorphism.
For $X=\hat{S}^{2 n} \omega_{\hat{S}^{2 n}}$ induces a nonfiltration preserving map $\omega$. $\omega$ is determined by

$$
\omega\left(\iota_{2 n-1}\right)=\iota_{2 n}, \quad \omega\left(x_{2 p n-2}\right)=h_{1}^{n} \otimes \iota_{2 n}
$$

where $\iota_{2 n}$ generates $B P_{2 n}\left(\hat{S}^{2 n}\right)$.
$\omega$ occurs in the middle column of the following commutative diagram

It follows from the 5 -lemma that $\omega$ is an isomorphism of spectral sequences (for $r \geqslant 3$ ), and $H$ therefore commutes with unstable Adams-Novikov differentials.

Remark 5.7. (i) $E_{2}^{s, t}\left(S^{2 n+1}\right)$ is $\bmod p$ meta-stable if

$$
t< \begin{cases}2(p-1) p k+2 p^{2} n+2, & s=2 k+1 \\ 2(p-1)(p k+1)+2 p^{2} n+2, & s=2 k+2\end{cases}
$$

In the $\bmod p$ meta-stable range there is a commutative ladder of exact sequences

$$
\begin{array}{cccccccc}
\rightarrow & E_{2}\left(\hat{S}^{2 n}\right) & \stackrel{\sigma}{\rightarrow} & E_{2}\left(S^{2 n+1}\right) & \xrightarrow{H^{\prime}} & E_{2}\left(S^{2 p n+1}\right) & \xrightarrow{P} & \cdots \\
& \downarrow H & & \downarrow H_{2} & & \| \sigma^{2} & & \\
\rightarrow & E_{2}\left(S^{2 p n-1}\right) & \xrightarrow{r} & \operatorname{Ext}_{थ}(A(2 p n-1) \otimes Z / p Z) & \xrightarrow{\delta} & E_{2}\left(S^{2 p n-1}\right) & \xrightarrow{x p} & \cdots
\end{array}
$$

where the bottom row is the Bockstein sequence, and $H^{\prime}$ is induced by the James map [8]. $H^{\prime}$ is therefore computed by (5.3) and the Bockstein differential (in the meta-stable range).
(ii) There is a spectral sequence

$$
\bigoplus_{i \geqslant 1} \operatorname{Ext}_{\mathcal{U}}\left(A\left(2 p^{i} n-1\right) \otimes Z / p Z\right) \Rightarrow \operatorname{Ext}_{\mathcal{U}}(W(n))
$$

with differentials given by (4.8). Together with the universal coefficient theorem and the results of $\S 5$ we have an inductive method for computing $E_{2}\left(S^{2 n+1}\right)$ which is similar to the computation in [16].
(iii) (5.3) is not useful for some infinite computations. For example, in order to compute the Hopf invariant of the stable elements constructed in [12] it is convenient to introduce an unstable version of the chromatic filtration (see [4]).

Appendix. With the formulas of $\S \S 4$ and 5 the unstable Adams-Novikov spectral sequence becomes a powerful tool for computing the homotopy groups of odd spheres (at least for $p>2$ ). Following is a table of the 3-primary unstable AdamsNovikov $E_{2}$ term through the 54 -stem. (The classical unstable Adams spectral sequence has approximately 3 times as many elements.)

Notation. (i) Elements in the table are listed by leading term in the sphere of origin filtration.
(ii) $\left(x h_{1}^{n}\right)_{y h_{1}^{m}}$ denotes an element on the $2 n+1$ sphere which is killed or made homologous to another class on the $2 m+1$ sphere. If the condition of (5.3)(ii) is satisfied $x$ and $y$ are the Hopf invariants (see Remark (i) below).
(iii)

$$
\begin{gathered}
X \\
\vdots \\
Y
\end{gathered}
$$

denotes an extension.
(iv) For $x$ a cycle, $\bar{x}$ denotes a cochain with $d \bar{x}=3 x$.
(v) In filtration 2, $\left\{\alpha_{n} h_{1}^{m}\right\}_{h_{1}^{n+m}}$ denotes the tower

$$
\begin{aligned}
& \left(\tilde{\alpha}_{n+m-1} h_{1}\right)_{v_{1}^{m-1} h_{1}^{n+1}} \\
& \vdots \\
& \left(\tilde{\alpha}_{n+1} h_{1}^{m-1}\right)_{v_{1} h_{1}^{n+m-1}} \\
& \vdots \\
& \left(\tilde{\alpha}_{n} h_{1}^{m}\right)_{h_{1}^{n+m}}
\end{aligned}
$$

where $\tilde{\alpha}_{k}$ is the generator of the image of the $J$ homomorphism in the $2(p-1) k-1$ stem in filtration 1.
(vi) We adopt the notation of [12] for the stable elements in filtrations 1 and 2. Their Hopf invariants are given by

$$
\begin{aligned}
\alpha_{m / n} & =v_{1}^{n-m} h_{1}^{n} \quad\left(\alpha_{m / 1}=\alpha_{m}\right), \quad \beta_{1}=\alpha_{1} h_{1}^{2} \\
\beta_{i} & =\overline{\beta_{i-1}} h_{1}^{4}, \quad i>1, \quad \beta_{3 / 3}=\alpha_{2} h_{1}^{7}, \quad \beta_{3 / 2}=\bar{\beta}_{1} h_{1}^{7} .
\end{aligned}
$$

(vii) The class $\alpha_{2} h_{1}^{4} \circ h_{1}^{2}$ in the 29 stem survives to $\beta_{2} \alpha_{1}$.

The class $\beta_{2} h_{1}^{3}$ suspends to $\beta_{3 / 3} \alpha_{1}\left(=\varepsilon^{\prime}\right)$ in the 37 -stem.
The class $\beta_{3 / 3} \circ h_{1}^{3}$ in the 45 -stem survives to the element $\phi$ in homotopy.
In the 48 -stem the class $\beta_{3 / 3} \alpha_{1} h_{1}^{3}$ does not suspend to zero in homotopy from $S^{9}$. In fact the class jumps filtration and suspends to $\beta_{1}^{3} \alpha_{1} h_{1}^{4}$.

In a similar way the class $\beta_{3 / 3} v_{1} h_{1}^{3}$ in the 49 -stem suspends to $\beta_{1}^{2} \alpha_{1} \beta_{2}$. The class $\beta_{3 / 3} v_{1} h_{1}^{4}$ in the 53 -stem suspends to $\beta_{1}^{3} v_{1} h_{1}^{5}$.

Remarks. (i) For elements in the tower defined in (v) above, one must be careful when reading the Hopf invariants of elements not in the meta-stable range (see 5.7). For example $\alpha_{9 / 3} h_{1} \in E_{2}^{2,43}\left(S^{3}\right)$ is not in the form required by 5.3(ii) $\left(\alpha_{9 / 3} \notin\right.$ $C^{*}(A(5) \otimes Z / p Z)$ ). We use the relation $\alpha_{9 / 3} h_{1}=\alpha_{8} \alpha_{2}$ to compute $H_{2}\left(\alpha_{9 / 3} h_{1}\right)=$ $\alpha_{8} v_{1}$. This is the first example of an unstable element in filtration two which is born on an odd sphere. A complete description of the unstable elements in filtration two will appear elsewhere.
(ii) If $\gamma=\sigma^{2} \delta$ then $H_{2}(\gamma x)=\gamma H_{2}(x)$ (see 5.3(ii)).

Low-dimensional computations. For convenience we desuspend the generators $y_{i}$ of $W(n)$ and use the isomorphism $\operatorname{Ext}_{\mathscr{Q}}(W(n)) \simeq \operatorname{Ext}_{\mathscr{\sim}}\left(\sigma^{-1} W(n)\right)$. We denote $\sigma^{-1} y_{i}$ by $x_{2 p^{i} n-1}$ and, by abuse of notation, denote $\sigma^{-1} W(n)$ by $\left\{x_{2 p n-1}, x_{2 p^{2} n-1}, \ldots\right\}$ where the only generators to be indicated will be those which are relevent for the range of computation being considered. For stem $t-s$ we compute the following part of the double suspension sequence:

$$
\begin{equation*}
\mathrm{Ext}^{s-2, t+2 n-1}\left(\left\{x_{2 p n-1}, \ldots\right\}\right) \xrightarrow{P} E_{2}^{s, t+2 n-1}\left(S^{2 n-1}\right) \tag{6.1}
\end{equation*}
$$

Both terms are inductively known. Elements in the image of $P$ suspend to zero on $S^{2 n+1}$. Elements in the kernel of $P$ produce elements on $S^{2 n+1}$ in the $s-t+1$ stem. The stem of $\operatorname{Ext}_{2}^{s, t}\left(\sigma^{-1} W(n)\right)$ is defined to be $t-s-(2 p n-1)$. As $n$ increases to $n+1$ in (6.1) the stem of $\operatorname{Ext}_{\text {U }}\left(\sigma^{-1} W(n)\right)$ decreases by $2(p-1)$. $P$ increases the stem by $2 n(p-1)-2$.

Finally we note that $E_{2}^{s, t}\left(S^{1}\right)=0$ if $(s, t) \neq(0,1)$.
The first stem greater than zero where there can be a nonzero group in (6.1) is the 3 -stem with $n=1, s=2$.
There is an element produced in the 3 -stem on $S^{3}$. The leading term of the generator is given taking the inverse of the map $H_{2}$. In this case we produce the generator $h_{1}$, which we denote by $\alpha_{1}$.

For dimension reasons there are no other elements in this stem.
The next nonzero groups occur in the 6 -stem. For $n=1$ the $P$ map increases stem by 2 . By induction the domain of the $P$-map is generated by $\alpha_{1}$, and we have an element $\alpha_{1}^{2}$ in the 6 -stem on $S^{3}$.

In stem 6 the domain of the $P$-map for $n=1$ is the 4 -stem which is generated in filtration zero by $v_{1}\left(=\bar{\alpha}_{1}\right)$. This produces an element with leading term $v_{1} h_{1}$ in the 7-stem which we call $\alpha_{2}$.

For $n=2$ the $P$-map shifts dimension by $6, d\left(x_{11}\right)=\alpha_{1}^{2}$ (up to a unit). So $\alpha_{1}^{2}$ dies on $S^{5}$.

The next interesting stem is the 10 -stem. For $n=1 P\left(\alpha_{2}\right)=0$, producing $\alpha_{2} \alpha_{1}$ on $S^{3}$ in the 10 -stem.

The stem shift for $n=2$ is 6 . So we need to compute $P\left(\alpha_{1} x_{11}\right)=\alpha_{1}^{3}=0$. Therefore an element $\beta_{1}$ with leading term $\alpha_{1} h_{1}^{2}$ is produced in the 10 -stem on $S^{5}$. Furthermore $3 \cdot \alpha_{1} h_{1}^{2}=h_{1} \cdot v_{1} h_{1}=v_{1} h_{1} \cdot h_{1}=\alpha_{2} \alpha_{1}$ modulo terms which desuspend, hence we obtain the extension indicated in the table.

The method of computation described thus far is sufficient to complete the table through the 12 -stem. In the 13 -stem there is the possibility of the first differential $\delta_{1}$ in the spectral sequence (5.7(ii)).

For $n=1$ we have

$$
\delta_{1}: \operatorname{Ext}^{0,17}(A(17) \otimes Z / p Z) \rightarrow \operatorname{Ext}^{1,17}(A(5) \otimes Z / p Z) \simeq Z / p Z\left\{\alpha_{3 / 2}, \overline{\alpha_{2} \alpha_{1}}\right\}
$$

(the computation of $\operatorname{Ext}^{1,17}(A(5) \otimes Z / p Z)$ is inductively determined from the table).

With $d$ the differential in the unstable cobar complex of $W(1)$ we have from (4.5),

$$
\delta_{1}\left(x_{17}\right)=p h_{1}^{3} \otimes x_{5}=\overline{\alpha_{2} \alpha_{1}} \otimes x_{5}
$$

(to see this we compute, using the table, $d\left(p h_{1}^{3}\right)=p\left(\alpha_{2} \alpha_{1}\right)$ ). We now have Ext ${ }^{1,17}(W(1)) \simeq Z / p Z\left\{\alpha_{3 / 2}\right\}$, and an element with Hopf invariant $\alpha_{3 / 2}$ is born on the 3 -sphere in the 14 -stem. (It is convenient to observe that the action (4.8) is unstable, so $\delta_{1}\left(x_{17}\right)$ cannnot be $\alpha_{3 / 2}$.)

Computations support the following conjecture (also observed by H. Miller):
Conjecture 6.2. The spectral sequence (5.7(ii)) collapses at $E_{2}$, and the natural $\operatorname{map} \operatorname{Ext}_{\text {थ }}(A(2 p n-1) \otimes Z / p Z) \rightarrow \operatorname{Ext}_{\mathcal{Q}}(W(n))$ is surjective.
6.2 is a useful "working principle" which can help motivate differentials in 5.7. Partial results relating to 6.2 will appear elsewhere.

It is convenient to use the stable Novikov spectral sequence [11] to simplify the computations on large stems. For example, in the 52 -stem, $\left(\beta_{2}\right)^{2}$ generates a stable $Z / p Z$. In order to get the correct result $P\left(\beta_{2} v_{1}\right)$ must be $\phi h_{1}^{2}$ or $\phi h_{1}^{2}-\beta_{2}^{2}$ on $S^{13}$. A stable computation $\bmod p$ shows that it is the latter.

Differentials. Differentials are determined by pulling back stable differentials, the multiplicative properties of the spectral sequence $[6,(4.9)]$ or by 5.6.

As a consequence of 5.6 the $d_{2}$ in the spectral sequence for $\Omega \hat{S}^{2 n}$ satisfies $d_{2}(x)=P(H(x))$ for $x \in E_{2}\left(\Omega \hat{S}^{2 n}\right)$. We conjecture the same remark is true for the unstable higher differentials in the spectral sequence for $\Omega \hat{S}^{2 n}$, and by 5.6 for the unstable higher differentials in the spectral sequence for $S^{k}$.

For example the element $\phi\left(=\beta_{3 / 3} h_{1}^{3}\right)$ in the 45 -stem is born in homotopy on $S^{9}$. The target of the differential is $P\left(\beta_{1}^{3}\right)$. The conjecture would imply that $H(\phi)=\beta_{1}^{3}$ in homotopy.

This may be seen from the table. The Hopf invariant is in the 30 -stem in filtration 3 or more. The only possibility is $\beta_{1}^{3}$.

If $d_{5}\left(\beta_{3 / 3}\right)$ were zero, and not $\beta_{1}^{3} \alpha_{1}$, then the double suspension sequences in homotopy and in Ext would be the same through the range of the table. A computation through the 52 -stem which assumed $\beta_{3 / 3}$ is a stable homotopy element was made by Brayton Gray [9].

$$
