LAYER POTENTIALS FOR ELASTOSTATICS AND HYDROSTATICS IN CURVILINEAR POLYGONAL DOMAINS

JEFF E. LEWIS

ABSTRACT. The symbolic calculus of pseudodifferential operators of Mellin type is applied to study layer potentials on a plane domain Ω^+ whose boundary $\partial\Omega^+$ is a curvilinear polygon. A “singularity type” is a zero of the determinant of the matrix of symbols of the Mellin operators and can be used to calculate the “bad values” of p for which the system is not Fredholm on $L^p(\partial\Omega^+)$.

Using the method of layer potentials we study the singularity types of the system of elastostatics

$$L\mathbf{u} = \mu\Delta\mathbf{u} + (\lambda + \mu)\nabla \operatorname{div} \mathbf{u} = 0.$$

in a plane domain Ω^+ whose boundary $\partial\Omega^+$ is a curvilinear polygon. Here $\mu > 0$ and $-\mu \leq \lambda \leq +\infty$. When $\lambda = +\infty$, the system is the Stokes system of hydrostatics. For the traction double layer potential, we show that all singularity types in the strip $0 < \operatorname{Re} z < 1$ lie in the interval $(\frac{1}{2}, 1)$ so that the system of integral equations is a Fredholm operator of index 0 on $L^p(\partial\Omega^+)$ for all p , $2 \leq p < \infty$. The explicit dependence of the singularity types on λ and the interior angles θ of $\partial\Omega^+$ is calculated; the singularity type of each corner is independent of λ iff the corner is nonconvex.

INTRODUCTION

Recently there has been considerable interest in using layer potentials to solve L^p boundary value problems for elliptic operators and systems on a Lipschitz domain Ω^+ in $\mathbf{R}^n$. For the systems of elastostatics [DKV] and hydrostatics [FKV], Dahlberg, Fabes, Kenig, and Verchota have used Rellich type identities to prove that the double layer potential integral equations yield a Fredholm operator of index 0 on $L^2(\partial\Omega^+)$. For $p \neq 2$ only limited information is available on the boundary integral equations for general Lipschitz domains in $\mathbf{R}^n$. The general problem of the notion of *symbol* on the boundary of a general Lipschitz domain is still very much open.

In this paper we treat a very special case: a curvilinear polygonal domain in $\mathbf{R}^2$. In this 2-dimensional case a precise symbolic calculus of pseudodifferential operators of Mellin type is available. We show that certain double layer boundary integral equations yield operators which for all p , $2 \leq p < \infty$, are

Fredholm operators of index 0 on $L^p(\partial\Omega^+)$. The singularities exhibited for $p < 2$ show the limitations of the general theory.

We develop the theory of double layer potentials for treating boundary value problems for second order elliptic systems in a plane domain Ω^+ which is bounded by a curvilinear polygon $\partial\Omega^+$. The double layer potential operators on $L^p(\partial\Omega^+)$ are interpreted as systems of pseudodifferential operators of Mellin type, or more simply *Mellin operators*, on $L^p(0, 1)$. A symbolic calculus for Mellin operators was developed by Lewis and Parenti [LP] and J. Elschner [E]. Our particular interest is to explicitly calculate the singularity types. A *singularity type* of a system of Mellin operators $\mathbf{K}$ is defined as a complex number z_0 , $\operatorname{Re} z_0 = \frac{1}{p}$, at which the determinant of the principal symbol, $\operatorname{Smb}^{\frac{1}{p}}(\mathbf{K})$, vanishes. Elschner [E] has used singularity types to construct parametrices and develop asymptotic expansions for solutions of the equation $\mathbf{K}\mathbf{f} = \mathbf{g}$. For a different approach to a symbol map on curves with corners, see Costabel [C].

In §1 we describe the algebra of Mellin operators on the finite interval $J \equiv [0, 1]$. We follow closely the notation of [E] since the parametrices have meromorphic symbols with poles at the singularity types.

In §2 we describe a class of double layer kernel operators and show that they are examples of Mellin operators; their principal symbols are calculated.

§3 gives a parametrization of a curvilinear polygon $\partial\Omega^+$ which reduces a system of double layer potential integral operators on $L^p(\partial\Omega^+)$ to a big system of operators of Mellin type on $L^p(J)$. The part of the symbol arising from each vertex P_k of $\partial\Omega^+$ is the same as for the corresponding operator in a plane sector of interior opening θ_k . Theorem 2 shows that the "bad values" of p for which the operators are not Fredholm on $L^p(\partial\Omega^+)$ are the same as for the sector problems; for the "good values" of p , the index of the system on $L^p(\partial\Omega^+)$ can be calculated from the change in argument of the principal symbol for the sector problems and Theorem 1 yields the index. Theorem 2 should be considered as a *localization* result.

In §4 we apply our results to for the system of linear elastostatics:

$$(0-1) \quad L\mathbf{u} = \mu\Delta\mathbf{u} + (\lambda + \mu)\nabla \operatorname{div} \mathbf{u} = 0.$$

The numbers μ and λ are the Lamé moduli; we assume $\mu > 0$ and that $-\mu \leq \lambda \leq +\infty$. When $\lambda = -\mu$, the operator L is two copies of the Laplace operator; when $\lambda = +\infty$, we interpret the operator as the Stokes system of hydrostatics:

$$(0-2) \quad \begin{cases} L(\mathbf{u}, p) = \mu\Delta\mathbf{u} - \nabla p = 0, \\ \operatorname{div} \mathbf{u} = 0. \end{cases}$$

Our interest is in the description of the singularities of solutions in terms of the interior angles θ at the vertices of $\partial\Omega^+$ and the parameter λ . We state our results in terms of the normalized parameter b , defined as

$$(0-3) \quad b = \frac{\lambda + \mu}{\lambda + 2\mu},$$

so that $0 \leq b \leq 1$.

The boundary operator of physical significance is the traction operator. The stress tensor $\mathbf{T} = (T_{i,k})$ is defined by

$$(0-6) \quad T_{i,k}(\mathbf{u}) = \lambda(\operatorname{div} \mathbf{u})\delta_{i,k} + \mu(u_{i,k} + u_{k,i}),$$

or in the case of the Stokes system ($\lambda = +\infty$),

$$(0-7) \quad T_{i,k}(\mathbf{u}, p) = -p(x)\delta_{i,k} + \mu(u_{i,k} + u_{k,i}),$$

where $u_{i,k} = \partial u_i / \partial x_k$. If $\vec{\nu}$ is the outward normal to Ω^+ at a point $P \in \partial\Omega^+$, the traction operator is

$$(0-8) \quad \mathbf{T}_{\vec{\nu}}(\mathbf{u}) = \mathbf{T}(\mathbf{u})\vec{\nu}.$$

We shall also consider another conormal boundary operator

$$(0-9) \quad \mathbf{N}_{\vec{\nu}}(\mathbf{u}) = \mu \frac{\partial \mathbf{u}}{\partial \vec{\nu}} + (\lambda + \mu)(\operatorname{div} \mathbf{u})\vec{\nu},$$

which for $b = 0$ reduces to the Neumann boundary operator. Let Ω^- denote the complement of $\Omega^+ \cup \partial\Omega^+$. The boundary value problems we shall treat are

(1) The Dirichlet problems $D_{\pm}$:

$$(0-10) \quad \begin{cases} L\mathbf{u} = 0 & \text{in } \Omega^{\pm}, \\ \mathbf{u}|_{\partial\Omega^{\pm}} = \mathbf{g} \in L^p(\partial\Omega^+). \end{cases}$$

(2) The traction problems $T_{\pm}$:

$$(0-11) \quad \begin{cases} L\mathbf{u} = 0 & \text{in } \Omega^{\pm}, \\ \mathbf{T}_{\vec{\nu}}(\mathbf{u})|_{\partial\Omega^{\pm}} = \mathbf{g} \in L^p(\partial\Omega^+). \end{cases}$$

(3) The Neumann problems $N_{\pm}$:

$$(0-12) \quad \begin{cases} L\mathbf{u} = 0 & \text{in } \Omega^{\pm}, \\ \mathbf{N}_{\vec{\nu}}(\mathbf{u})|_{\partial\Omega^{\pm}} = \mathbf{g} \in L^p(\partial\Omega^+). \end{cases}$$

We represent the solutions of $D_{\pm}$ as double layer potentials and the solutions of $T_{\pm}$ and $N_{\pm}$ as single layer potentials using the fundamental solution given by Kupradze [K, Chapter 9, (9.2)]:

$$(0-13) \quad \Gamma(X) = (\Gamma_{i,j}(X)) = \left(\delta_{i,j} \frac{n}{2\pi} \log r^2 - \frac{m}{\pi} \frac{x_i x_j}{r^2} \right),$$

with $r^2 = x_1^2 + x_2^2$ and

$$(0-14) \quad n = \frac{\lambda + 3\mu}{2\mu(\lambda + 2\mu)}, \quad m = \frac{\lambda + \mu}{2\mu(\lambda + 2\mu)}.$$

This fundamental solution satisfies

$$(0-15) \quad L(\Gamma(X)) = 2\delta(X)\mathbf{I},$$

where the operator L is applied to the columns of the matrix Γ . When $b = 1$, we have $n = m$ and as in Ladyzhenskaya [La, Chapter 3] introduce the fundamental pressure (row) vector:

$$\mathbf{q}(X) = \frac{1}{\pi} \frac{X}{r^2},$$

so that $\{\Gamma, \mathbf{q}\}$ is a solution of the adjoint Stokes system

$$(0-16) \quad \begin{cases} \mu \Delta \Gamma + \nabla \mathbf{q} = 2 \delta(X) \mathbf{I}, \\ \operatorname{div} \Gamma = 0. \end{cases}$$

The solution of $D_{\pm}$ is sought in the form of the double layer potential

$$(0-17)^1 \quad \mathbf{u}_T(X) = \int_{\partial\Omega^+} \mathbf{T}_{\vec{\nu}(Q)}(\Gamma(X - Q)) \mathbf{f}(Q) d\sigma_Q.$$

Taking nontangential limits in $L^p(\partial\Omega^+)$ from inside and outside Ω^+ , and calling the resulting limits $\mathbf{u}_T^{\pm}$, we obtain

$$(0-18) \quad \mathbf{u}_T^{\pm}(P) \equiv \mathbf{K}_T^{\pm} \mathbf{f}(P) = \pm \mathbf{I} \mathbf{f}(P) + \text{p.v.} \int_{\partial\Omega^+} \mathbf{T}_{\vec{\nu}(Q)}(\Gamma(P - Q)) \mathbf{f}(Q) d\sigma_Q,$$

where even in the case where $\partial\Omega^+$ is flat the integral operator in (0-18) is not compact.

In a like manner the solutions of $T_{\pm}$ and $N_{\pm}$ are represented in the form of a single layer potential

$$(0-19) \quad \mathbf{u}_S(X) = - \int_{\partial\Omega^+} \Gamma(X - Q) \mathbf{f}(Q) d\sigma_Q.$$

Applying the boundary operators $\mathbf{T}_{\pm}$ and $\mathbf{N}_{\pm}$ to $\mathbf{u}_S$ we obtain integral equations which are adjoints to the double layer integral equations; e.g.,

$$[\mathbf{T}_{\pm}(\mathbf{u}_S) \vec{\nu}](P) = (\mathbf{K}_T^{\mp})^* \mathbf{f}(P).$$

In §4 we give explicit expressions for the kernels for elastostatics and hydrostatics in a plane sector.

In §5 we compute the symbols for the problems in a plane sector. Theorem 7 gives a very simple expression for the determinant of the matrix of symbols in terms of the parameter b and the interior angle θ .

In §6, we calculate the singularity types of $\mathbf{K}_T^{\pm}$. We first summarize the results in a plane sector in Theorem 8. Theorem 8 shows that there is a contrast in the cases of a corner of Ω^+ where Ω^+ is convex ($0 < \theta < \pi$), and the case of a reentrant corner ($\pi < \theta < 2\pi$). We first note that when $b = 0$, the operator $\mathbf{T}_{\vec{\nu}}$ does not cover L ; however, $\mathbf{N}_{\vec{\nu}}$ covers L for $0 \leq b \leq 1$. The nature of the singularity types is

¹In the case $b = 1$, the kernel $\mathbf{T}_{\vec{\nu}(Q)}(\Gamma(X - Q))$ is replaced by

$$\mathbf{T}'_{\vec{\nu}(Q)}(\Gamma(X - Q), \mathbf{q}) \equiv (\mathbf{q} \delta_{i,k} + \mu(\Gamma_{i,k} + \Gamma_{k,i})) \vec{\nu}(Q),$$

the stress tensor being applied to the columns of $\{\Gamma, \mathbf{q}\}$.

Case I. For $0 < \theta < \pi$, the Mellin operators $\mathbf{K}_T^+$ and $\mathbf{K}_N^+$ have the same singularities for $0 < b \leq 1$. For $0 < b < 1$, there are two singularity types in the strip $0 < \operatorname{Re} z < 1$; both singularity types are real and lie in $(\frac{1}{2}, 1)$. When $b = 1$, there is a value $\gamma_{\text{crit}} \approx 257^\circ 27'$ for which there are two singularity types for $0 < \theta < 2\pi - \gamma_{\text{crit}}$; for $2\pi - \gamma_{\text{crit}} \leq \theta < \pi$, there is only one singularity type in the strip.

Case II. For $\pi < \theta < 2\pi$, the singularity types for $\mathbf{K}_T^+$ in the strip $0 < \operatorname{Re} z < 1$ are independent of b , lie in $(\frac{1}{2}, 1)$ and approach $\frac{1}{2}$ as θ approaches 2π ; there is one singularity type in the strip for $\pi < \theta \leq \gamma_{\text{crit}}$; a second singularity type develops for $\gamma_{\text{crit}} < \theta < 2\pi$.

Finally, Theorem 9 summarizes the “good values” and “bad values” of p for the double layer potential integral equations on $L^p(\partial\Omega^+)$, where $\partial\Omega^+$ is a curvilinear polygon.

1. MELLIN OPERATORS ON A FINITE INTERVAL

Algebras of Mellin operators on $J \equiv [0, 1]$ are defined in [LP, Definition (4.1)] and [E, Definition (4.1)]. We follow closely the notions of [E] since Elschner develops an extension to meromorphic symbols which arise in constructing parametrices. For $0 \leq \alpha < \beta \leq 1$, define the strip $\Gamma_{\alpha, \beta} = \{z \in \mathbb{C} : \alpha < \operatorname{Re} z < \beta\}$, and let Γ_γ be the line $\{z = \gamma + i\xi : -\infty \leq \xi \leq +\infty\}$. The symbol space $\tilde{\Sigma}_{\alpha, \beta}^0$ is defined in [E, Definition (1.12)].

For $f \in C_0^\infty(\mathbb{R}^+)$ define the *Mellin transform* of f by

$$(1-1) \quad \mathcal{M}f(z) = \tilde{f}(z) = \int_0^\infty t^{z-1} f(t) dt.$$

Let $\partial = -td/dt$, and for $a \in \tilde{\Sigma}_{\alpha, \beta}^0$, we define the Mellin operator $a(t, \partial) \in \operatorname{Op} \tilde{\Sigma}_{\alpha, \beta}^0$ by

$$(1-2) \quad a(t, \partial)f(t) = \frac{1}{2\pi i} \int_{\operatorname{Re} z = \gamma} t^{-z} a(t, z) \tilde{f}(z) dz,$$

with $\gamma \in (\alpha, \beta)$.

If $f \in L^p(J)$ let Rf be the reflection

$$(1-3) \quad Rf(t) = f(1-t).$$

Definition 1.1. An operator A from $C_0^\infty(J)$ to $C^\infty(J)$ is a Mellin operator in the class $\operatorname{Op} \Sigma_{\alpha, \beta}(J)$ iff

- (1) For all $\phi, \psi \in C_0^\infty([0, 1])$, there are operators $a_{0\phi\psi}(t, \partial) \in \operatorname{Op} \tilde{\Sigma}_{\alpha, \beta}^0$ and $C_{0\phi\psi}$, compact on $L^p(J)$ for all p with $\frac{1}{p} \in (\alpha, \beta)$, such that

$$(1-4) \quad \phi A \psi = a_{0\phi\psi}(t, \partial) + C_{0\phi\psi}.$$

- (2) If $\phi, \psi \in C^\infty([0, 1])$ have disjoint supports, the operator $\phi A \psi$ is compact on $L^p(J)$, $\frac{1}{p} \in (\alpha, \beta)$.

- (3) The operator $A^R \equiv RAR$ satisfies conditions (1) and (2).

To define the *principal symbol*, $\text{Smb}^{\frac{1}{p}}(A)$, for A as an operator on $L^p(J)$, we use that there are uniquely defined functions $a_0(z)$, $a_{0\pm}(t)$ such that for all $\phi, \psi \in C_0^\infty([0, 1])$,

$$(1-5) \quad \begin{aligned} a_{0\phi\psi}(0, z) &= \phi(0)a_0(z)\psi(0), & z \in \Gamma_{\alpha, \beta}, \\ a_{0\phi\psi}(t, \tfrac{1}{p} \pm i\infty) &= \phi(t)a_{0\pm}(t)\psi(t), & 0 \leq t < 1, \tfrac{1}{p} \in (\alpha, \beta). \end{aligned}$$

There are uniquely defined functions $a_1(z)$, $a_{1\pm}(t)$ such that for all $\phi, \psi \in C_0^\infty([0, 1])$,

$$(1-6) \quad \begin{aligned} (a^R)_{0\phi\psi}(0, z) &= \phi(0)a_1(z)\psi(0), & z \in \Gamma_{\alpha, \beta}, \\ (a^R)_{0\phi\psi}(t, \tfrac{1}{p} \pm i\infty) &= \phi(t)a_{1\pm}(t)\psi(t), & 0 \leq t < 1, \tfrac{1}{p} \in (\alpha, \beta). \end{aligned}$$

Moreover

$$(1-7) \quad a_{0\pm}(t) = a_{1\mp}(1 - t), \quad 0 < t < 1.$$

Let $\mathcal{R}_J^{\frac{1}{p}}$ be the oriented boundary of the rectangle:

$$(1-8) \quad \begin{array}{ccccc} & t=0 & t \in [0, 1] & t=1 & \\ \frac{1}{p} + i\infty & & & & \frac{1}{p} - i\infty \\ & \uparrow & \mathcal{R}_J^{\frac{1}{p}} & \downarrow & \\ \Gamma_{\frac{1}{p}} & & & & \Gamma_{\frac{1}{p}} \\ \frac{1}{p} - i\infty & & & & \frac{1}{p} + i\infty \\ & t=0 & t \in [0, 1] & t=1 & \end{array}$$

Definition 1.2. Let $A \in \text{Op } \Sigma_{\alpha, \beta}(J)$ and $\frac{1}{p} \in (\alpha, \beta)$. The principal symbol of A as an operator on $L^p(J)$, $\text{Smb}^{\frac{1}{p}}(A)$, is the quadruple of functions $a_0(\frac{1}{p} + i\xi)$, $a_{0+}(t) = a_{1-}(1 - t)$, $a_1(\frac{1}{p} + i\xi)$, $a_{0-}(t) = a_{1+}(1 - t)$, considered as a continuous function on $\mathcal{R}_J^{\frac{1}{p}}$:

$$(1-9) \quad \begin{array}{ccccc} & t=0 & a_{0+}(t) = a_{1-}(1 - t) & t=1 & \\ \frac{1}{p} + i\infty & & & & \frac{1}{p} - i\infty \\ & \uparrow & \mathcal{R}_J^{\frac{1}{p}} & \downarrow & \\ a_0(\frac{1}{p} + i\xi) & & & & a_1(\frac{1}{p} + i\xi) \\ \frac{1}{p} - i\infty & & & & \frac{1}{p} + i\infty \\ & t=0 & a_{0-}(t) = a_{1+}(1 - t) & t=1 & \end{array}$$

Definition 1.3. Let $A = (A_{ij})$ be an $N \times N$ matrix of operators in $\text{Op } \Sigma_{\alpha, \beta}(J)$. The system A is elliptic on $L^p(J)$ ² iff $\text{Smb}^{\frac{1}{p}} A$ is a nonsingular matrix on $\mathcal{R}_J^{\frac{1}{p}}$. A number $z_0 \in \Gamma_{\alpha, \beta}$ is a singularity type for A at $t=0$ [$t=1$] if

$$(1-10) \quad \det(\text{Smb}^{\frac{1}{p}}(A)(0, z_0)) = 0 \quad [\det(\text{Smb}^{\frac{1}{p}}(A)(1, z_0)) = 0].$$

²For brevity we write $L^p(J)$ for $[L^p(J)]^N$.

The following is shown in [E, Theorems 4.4 and 4.6] and [LP, Theorems 4.1 and 4.2].

Theorem 1. *Let $A = (A_{ij})$ be an $N \times N$ matrix of operators in $\text{Op } \Sigma_{\alpha, \beta}(J)$. Then*

- (1) *A is a Fredholm operator on $L^p(J)$ iff A is elliptic on $L^p(J)$.*
- (2) *If A is elliptic on $L^p(J)$, define*

$$(1-11) \quad \text{ind}_p(A) = \dim((\ker A) \cap L^p(J)) - \dim((\ker A^*) \cap L^{p/p-1}(J)).$$

Then

$$(1-12) \quad \text{ind}_p(A) = \frac{1}{2\pi} \Delta_{\mathcal{R}_J^{\frac{1}{p}}} \{ \arg(\det(\text{Smb}^{\frac{1}{p}} A)) \},$$

where the change in $\arg$ is taken as $\mathcal{R}_J^{\frac{1}{p}}$ is traversed in the clockwise direction.

Remark. In treating boundary value problems in domains with corners it is useful to regard Mellin operators as acting on weighted spaces, e.g., $L^{p, \sigma}(J) \equiv \{f: t^\sigma f(t) \in L^p(J)\}$. In this case we suppose that both $\frac{1}{p} + \sigma$ and $\frac{1}{p}$ lie in (α, β) . The *principal symbol* would be defined on the oriented rectangle $\mathcal{R}_J^{\frac{1}{p} + \sigma, \frac{1}{p}}$ whose left-hand side is the contour $\Gamma_{\frac{1}{p} + \sigma}$, and whose right-hand side is the contour $\Gamma_{\frac{1}{p}}$. Cf. [E], but note that our notation differs slightly from [E, (4.8) ff.]. The approach of weighted spaces is especially useful where different weights may be introduced at different vertices of a polygon.

When double layer potentials on a curvilinear polygon $\partial\Omega^+$ are reduced to a system of Mellin operators as in §3, the operators near $t = 1$ will correspond to a smooth part of $\partial\Omega^+$ so that singularities at $t = 1$ will not appear; the change in $\arg$ of $\det(\text{Smb}^{\frac{1}{p}} A)$ will occur entirely on the contour $\Gamma_{\frac{1}{p}}$ on the left-hand side of (1-8).

2. EXAMPLES OF MELLIN OPERATORS

In this section we give examples of Mellin operators in $\text{Op } \Sigma_{0,1}(J)$.

1. The finite Hilbert transform H is defined by

$$(2-1) \quad Hf(t) = \text{p.v.} \frac{1}{\pi} \int_0^1 \frac{f(s)}{t-s} ds.$$

H is in $\text{Op } \Sigma_{0,1}(J)$ and $\text{Smb}^{\frac{1}{p}} H$ is

$$(2-2) \quad \begin{array}{ccccc} & t=0 & +i & t=1 & \\ \frac{1}{p} + i\infty & & & & \frac{1}{p} - i\infty \\ -\cot \pi z & \uparrow & \mathcal{R}_f^{\frac{1}{p}} & \downarrow & +\cot \pi z \\ \frac{1}{p} - i\infty & & & & \frac{1}{p} + i\infty \\ & t=0 & -i & t=1 & \end{array}$$

2. Let $k(t) \in \mathcal{F}'_{-\infty,1}$ [LP, Definition 1.1]; i.e., $k(t) \in C^\infty([0, \infty))$ and for every $l \geq 0$, $\delta > 0$, $\partial^l k(t) = O(t^{-1+\delta})$ as $t \rightarrow \infty$. Define the *Hardy kernel operator* by

$$(2-3) \quad Kf(t) = \int_0^1 k\left(\frac{t}{s}\right) f(s) \frac{ds}{s}.$$

Then $K \in \text{Op } \Sigma_{0,1}(J)$ and $\text{Smb}^{\frac{1}{p}} K$ is

$$(2-4) \quad \begin{array}{ccccc} & t=0 & 0 & t=1 & \\ \frac{1}{p} + i\infty & & & & \frac{1}{p} - i\infty \\ \tilde{k}(z) & \uparrow & \mathcal{R}_f^{\frac{1}{p}} & \downarrow & 0 \\ \frac{1}{p} - i\infty & & & & \frac{1}{p} + i\infty \\ & t=0 & 0 & t=1 & \end{array}$$

Definition 2.1. A function $k(x, y)$ is a *double layer kernel* if

- (1) $k \in C^\infty(\mathbf{R}^2 \setminus \{0\})$,
- (2) k is homogeneous of degree -1 and odd: for all $\lambda \neq 0$, $k(\lambda x, \lambda y) = \lambda^{-1} k(x, y)$.

3. Let $k(x, y)$ be a double layer kernel and $0 < \theta < 2\pi$. Define

$$(2-5) \quad K_\theta f(t) = \int_0^1 k(t - s \cos \theta, -s \sin \theta) f(s) ds.$$

Then K_θ is a Hardy kernel operator with kernel

$$(2-6) \quad k_\theta(t) = k(t - \cos \theta, -\sin \theta).$$

4. Let $k(x, y)$ be a double layer kernel. Then

$$(2-7) \quad \lim_{y \rightarrow 0^\pm} \int_0^1 k(t - s, y) f(s) ds = \pm c_k f(t) + \pi k(1, 0) H f(t),$$

where

$$(2-8) \quad c_k = \lim_{R \rightarrow \infty} \int_{-R}^R k(x, 1) dx = \lim_{\varepsilon \rightarrow 0^+} \int_\varepsilon^{\pi-\varepsilon} \frac{k(\cos \theta, \sin \theta)}{\sin \theta} d\theta.$$

This is simply the observation that if we let

$$\phi(t) = \begin{cases} k(t, 1) - k(1, 0)/t, & |t| > 1, \\ k(t, 1), & |t| < 1, \end{cases}$$

then $\phi(t) = O(1/t^2)$ as $|t| \rightarrow \infty$, so that $\phi \in L^1(\mathbf{R})$. The function

$$\frac{1}{y} \int_0^1 \phi\left(\frac{t-s}{y}\right) f(s) ds$$

is dominated by the Hardy-Littlewood maximal function of f and approaches $\pm(\int \phi(x) dx)f$ in $L^p(J)$ (cf. Stein [St]). Since $k(x, 0) = k(1, 0)/x$ is an odd function, $(\int \phi(x) dx)$ is given by (2-8).

5. Let $k(x, y)$ be a double layer kernel. Let $\vec{\gamma}_j$, $j = 1, 2$, be two C^∞ curves which intersect only at $(0, 0)$. Assume that $d\vec{\gamma}_j/dt|_{t=0} = \vec{u}_j$ are unit vectors, $\vec{u}_1 \neq \vec{u}_2$, so that $\vec{\gamma}_j(t) = t\vec{u}_j + \vec{e}_j(t)$, with $\vec{e}_j(t) = O(t^2)$. Let

$$(2-9) \quad K^{12}f(t) = \int_0^1 k(\vec{\gamma}_1(t) - \vec{\gamma}_2(s))f(s) \left| \frac{d\vec{\gamma}_2}{ds} \right| ds.$$

Then K^{12} is a Mellin operator whose principal symbol is the same as that of the Hardy kernel operator with kernel

$$k^{12}(t) = k(t\vec{u}_1 - \vec{u}_2).$$

To show this we assume $\vec{u}_1 = (1, 0)$ and $\vec{u}_2 = (\cos \theta, \sin \theta)$, $0 < \theta < 2\pi$. Then $k(\vec{\gamma}_1(t) - \vec{\gamma}_2(s)) = k(t - s \cos \theta, -s \sin \theta) + R(t, s)$, where

$$(2-10) \quad R(t, s) = \int_0^1 \vec{e}(t, s) \cdot \nabla k((t - s \cos \theta, -s \sin \theta) + \tau \vec{e}(t, s)) d\tau$$

with $\vec{e}(t, s) = \vec{e}(t) - \vec{e}(s)$. Since $|\vec{\gamma}_1(t) - \vec{\gamma}_2(s)| \approx t + s$, we can differentiate wrt t to show that

$$f(t) \mapsto \frac{d}{dt} \int_0^1 R(t, s) f(s) ds$$

can be dominated by a Hardy kernel operator. Hence $f(t) \mapsto \int_0^1 R(t, s) f(s) ds$ is a compact operator on $L^p(J)$.

6. Let $\vec{\gamma}(t)$, $0 \leq t \leq 1$, be a C^∞ curve and $k(x, y)$ a double layer kernel. Let

$$(2-11) \quad K_{\vec{\gamma}}f(t) = \text{p.v.} \int_0^1 k(\vec{\gamma}(t) - \vec{\gamma}(s))f(s) \left| \frac{d\vec{\gamma}}{ds} \right| ds.$$

Then $K_{\vec{\gamma}} \in \text{Op } \Sigma_{0,1}(J)$ and has the same symbol as $\pi k(\vec{\gamma}'(t))|d\vec{\gamma}/dt|H$. Observe that if $\vec{\gamma}(t) - \vec{\gamma}(s) = \vec{\gamma}'(t)(t-s) + \vec{e}(t, s)$, then

$$k(\vec{\gamma}(t) - \vec{\gamma}(s)) - \frac{k(\vec{\gamma}'(t))}{t-s} = \int_0^1 \vec{e}(t, s) \cdot \nabla k(\vec{\gamma}'(t)(t-s) + \tau \vec{e}(t, s)) d\tau,$$

which gives rise to a compact operator on $L^p(J)$.

7. In Example 6 assume that $\vec{\gamma}$ is smooth for $-1 \leq t \leq +1$ and $d\vec{\gamma}(0)/dt = \vec{u}$. For $0 \leq t \leq 1$, let $\vec{\gamma}_1(t) = \vec{\gamma}(t)$, $\vec{\gamma}_2(t) = \vec{\gamma}(-t)$. The operator K^{12} of (2-9) has the same symbol as the Hardy kernel $k(\vec{u})\frac{1}{t+1}$. The kernel $s(t) = \frac{1}{\pi} \frac{1}{t+1}$ is the kernel for the Stieltjes transform and $\hat{s}(z) = \csc \pi z$ [LP, (4.30)]. In particular, if we break a smooth curve $\vec{\gamma}(t)$, $-1 \leq t \leq 1$ at $t = 0$ the Hilbert transform p.v. $\int_{-1}^{+1} k(\vec{\gamma}(t) - \vec{\gamma}(s))f(s)|d\vec{\gamma}/ds| ds$ is equivalent to the matrix of operators

$$(2-12) \quad K = \begin{pmatrix} H_{\vec{\gamma}_1} & K^{12} \\ K^{21} & H_{\vec{\gamma}_2} \end{pmatrix},$$

which has principal symbol at $t = 0$ given by

$$(2-13) \quad \pi k(\vec{u}) \times \begin{pmatrix} -\cot \pi z & \csc \pi z \\ -\csc \pi z & \cot \pi z \end{pmatrix}.$$

Note that the characteristic polynomial of the matrix in (2-13) is $p(\lambda) = (\lambda + i)(\lambda - i)$.

3. LAYER POTENTIALS ON CURVILINEAR POLYGONS

Let Ω^+ be a simply connected³ domain in $\mathbf{R}^2$ whose boundary is a simple closed curvilinear polygon. As $\partial\Omega^+$ is traversed in the counterclockwise direction label the successive N vertices as $P_2, P_4, \dots, P_{2N} = P_0$. Let $\overrightarrow{P_i P_j}$ be the oriented piece of $\partial\Omega^+$ between P_i and P_j . Suppose that $\overrightarrow{P_{2k} P_{2k+2}}$ is parametrized by $\vec{\gamma}(t)$, $0 \leq t \leq 2$. For $k = 1, \dots, N$, we introduce the false vertices $P_{2k-1} = \vec{\gamma}_{2k-2}(1)$ and then parametrize $\overrightarrow{P_{2k} P_{2k-1}}$ by $\vec{\gamma}_{2k-1}(t) \equiv \vec{\gamma}_{2k-2}(2-t)$, $0 \leq t \leq 1$. When $t = 0$ each parametrization is at one of the original vertices; if $t = 1$, we are at a "midpoint". For $i = 1, \dots, 2N$, let θ_i be the angle interior to Ω^+ at P_i , $0 < \theta_i < 2\pi$; of course $\theta_{2k-1} = \pi$. We assume that at $t = 0, 1$, $d\vec{\gamma}_j/dt$ are unit vectors; the arclength on $\overrightarrow{P_i P_{i+1}}$ is given by $d\sigma = (-1)^i |d\vec{\gamma}_i/dt| dt$.

For f a scalar or vector function in $L^p(\partial\Omega^+)$, we define $f^i(t) = f(\vec{\gamma}_i(t))$, $0 \leq t \leq 1$, $i = 1, \dots, 2N$.

Assume that $c(x, y)$ is scalar or matrix function such that for each i , $i = 1, \dots, 2N$, $c^i(t) = c(\vec{\gamma}_i(t))$ is a smooth function. Let $k(x, y)$ be an odd double layer kernel. We define the *double layer potential*

$$(3-1) \quad Kf(P) = c(P)f(P) + \text{p.v.} \int_{\partial\Omega^+} k(P-Q)f(Q) d\sigma_Q.$$

Let

$$(3-2) \quad K^{i,j} f^j(t) = \delta_{i,j} c^j(t) f^j(t) + \text{p.v.} \int_0^1 k(\vec{\gamma}_i(t) - \vec{\gamma}_j(s)) f^j(s) (-1)^j \left| \frac{d\vec{\gamma}_j}{ds} \right| ds,$$

³If Ω^+ is multiply connected we apply the method to each component of $\partial\Omega^+$.

so that

$$(Kf)^i(t) = \sum_{j=1}^{2N} K^{i,j} f^j(t);$$

we write $\mathbf{K} = (K^{i,j})_{i,j=1,\dots,2N}$ for the operator K interpreted as a big system of Mellin operators on $L^p(J)$.

Except in the cases $j = i - 1, i, i + 1 \pmod{2N}$, the operators $K^{i,j}$ have smooth kernels and thus are compact operators on $L^p(J)$. The operators $K^{2k,2k-1}$ and $K^{2k-1,2k}$ are Hardy kernel operators whose symbol is calculated by (2-7); in particular their principal symbol vanishes for $t > 0$. The operators $K^{2k,2k+1}$ and $K^{2k+1,2k}$ have principal symbol which vanishes for $0 < t < 1$; near $t = 1$, to calculate $\det(\text{Smb}^{\frac{1}{p}}(\mathbf{K}))$, we can apply an even number of row and column transpositions to reduce the symbol matrix to 2×2 block diagonal form. After applying the reflection (1-3), we are again reduced to considering the previous case at $t = 0$ with angle $\theta_{2k+1} = \pi$. The determinants of the matrix of principal symbols are summarized in Theorem 2.

Theorem 2. For $i = 1, \dots, 2N, \pmod{2N}$, let $K^{(i)}$ denote the matrix of blocks

$$(3-3) \quad K^{(i)} = \begin{pmatrix} K^{i-1,i-1} & K^{i-1,i} \\ K^{i,i-1} & K^{i,i} \end{pmatrix}.$$

Then at $t = 0$,

$$(3-4) \quad \det(\text{Smb}^{\frac{1}{p}}(\mathbf{K})) = \prod_{i=1}^N \det(\text{Smb}^{\frac{1}{p}}(K^{(2i)})).$$

At $t = 1$,

$$(3-5) \quad \det(\text{Smb}^{\frac{1}{p}}(\mathbf{K})) = \prod_{i=1}^N \det(\text{Smb}^{\frac{1}{p}}(K^{(2i-1)})).$$

At $z = \frac{1}{p} \pm i\infty$,

$$(3-6) \quad \det(\text{Smb}^{\frac{1}{p}}(\mathbf{K})) = \prod_{i=1}^{2N} \det(\text{Smb}^{\frac{1}{p}}(K^{i,i})).$$

4. ELASTOSTATIC DOUBLE LAYER POTENTIALS IN A PLANE SECTOR

We give explicit calculations for the double layer potentials for the system of elastostatics and hydrostatics in a plane sector. In this section we fix θ , $0 < \theta < 2\pi$, and let Ω^+ be the sector of opening θ :

$$(4-1) \quad \Omega^+ = \{(x, y) : x = r \cos \phi, y = r \sin \phi, 0 < r < \infty, 0 < \phi < \theta\}.$$

Denote the two pieces of $\partial\Omega^+$ as $S_1 = \{(\tau, \rho) : \tau > 0, \rho = 0\}$ and $S_2 = \{(\tau, \rho) : \tau = l \cos \theta, \rho = l \sin \theta, l > 0\}$. We denote by $\vec{\nu}_1 = -\mathbf{j}$ and

$\vec{\nu}_2 = -\sin \theta \mathbf{i} + \cos \theta \mathbf{j}$ the exterior normals to Ω^+ along S_1 and S_2 . For a vector function $\mathbf{f} \in L^p(\partial\Omega^+)$, let $\mathbf{f}^1(t) = \mathbf{f}(t, 0)$, $\mathbf{f}^2(t) = \mathbf{f}(t \cos \theta, t \sin \theta)$.

For $(t, s) \notin \partial\Omega^+$, the double layer potential is defined as in (0-17):

$$\begin{aligned} \mathbf{u}_T(t, s) &= \int_{\partial\Omega^+} \mathbf{T}_{\vec{\nu}(\tau, \rho)}(\Gamma(t - \tau, s - \rho)) \mathbf{f}(\tau, \rho) d\sigma_{\tau, \rho} \\ (4-2) \quad &= \int_0^\infty \mathbf{T}_{\vec{\nu}_1}(\Gamma(t - \tau, s)) \mathbf{f}^1(s) d\tau \\ &\quad + \int_0^\infty \mathbf{T}_{\vec{\nu}_2}(\Gamma(t - l \cos \theta, s - l \sin \theta)) \mathbf{f}^2(l) (-1) dl. \end{aligned}$$

We have

$$(4-3) \quad \lim_{s \rightarrow 0^\pm} \mathbf{u}_T(t, s) = (\mathbf{u}_T^\pm)^1(t) = \mathbf{K}_T^{\pm 11} \mathbf{f}^1(t) + \mathbf{K}_T^{12} \mathbf{f}^2(t),$$

where

$$\begin{aligned} (4-4) \quad \mathbf{K}_T^{\pm 11} \mathbf{f}^1(t) &= \pm \mathbf{I} \mathbf{f}^1(t) + \text{p.v.} \int_0^\infty \mathbf{T}_{\vec{\nu}_1(\tau, \rho)}(\Gamma(t - \tau, 0)) \mathbf{f}^1(\tau) d\tau, \\ \mathbf{K}_T^{12} \mathbf{f}^2(t) &= - \int_0^\infty \mathbf{T}_{\vec{\nu}_2(\tau, \rho)}(\Gamma(t - l \cos \theta, s - l \sin \theta)) \mathbf{f}^2(l) dl. \end{aligned}$$

The singular integral operators in $\mathbf{K}_T^{\pm 11}$ are multiples of the Hilbert transform by (2-6) and the operator $\mathbf{K}_T^{12}$ is a 2×2 matrix of Hardy kernel operators with $\text{Smb}^{\frac{1}{p}}(\mathbf{K}_T^{12})$ near $t = 0$ given by the Mellin transform of the kernel. When the identity $\mathbf{I}$ and the Hilbert transform are considered as Mellin operators, their kernels are the distributions $\delta(t - 1)$ and $h(t) = \text{p.v.} \frac{1}{\pi} \frac{1}{t-1}$ respectively.

For $(t, 0) \in S_1$ and $(\cos \theta, \sin \theta) \in S_2$, we define

$$(4-5) \quad d^2 = t^2 - 2t \cos \theta + 1 = (t - \cos \theta)^2 + \sin^2 \theta.$$

For $j = 0, 1, 2, 3$, let

$$(4-6) \quad k_j(t) = \frac{1}{\pi} \frac{(t - \cos \theta)^j (\sin \theta)^{3-j}}{d^4}.$$

Let $\mathcal{E}(x, y)$ be one of the scalar kernels in the matrix fundamental solution (0-13). Then $k_{\mathcal{E}_\rho} = -\frac{\partial \mathcal{E}}{\partial y}$ and $k_{\mathcal{E}_\tau} = -\frac{\partial \mathcal{E}}{\partial x}$ are double layer kernels according to (Definition 2.1). We consider the following scalar double layer potentials:

$$\begin{aligned} (4-9) \quad u_{\mathcal{E}_\rho}(t, s) &= \int_{\partial\Omega^+} \frac{\partial}{\partial \rho} \{\mathcal{E}(t - \tau, s - \rho)\} f(\tau, \rho) d\sigma_{\tau, \rho}, \\ u_{\mathcal{E}_\tau}(t, s) &= \int_{\partial\Omega^+} \frac{\partial}{\partial \tau} \{\mathcal{E}(t - \tau, s - \rho)\} f(\tau, \rho) d\sigma_{\tau, \rho}. \end{aligned}$$

Taking limits as $s \rightarrow 0^\pm$, we obtain the following Mellin operators on $L^p(\mathbf{R}^+)$:

$$\begin{aligned} (4-10) \quad K_{\mathcal{E}_\rho}^{\pm 11} f^1(t) &= \lim_{s \rightarrow 0^\pm} \int_0^\infty -\frac{\partial \mathcal{E}}{\partial y}(t - \tau, s) f^1(\tau) d\tau = \int_0^\infty k_{\mathcal{E}_\rho}^{\pm 11} \left(\frac{t}{\tau}\right) f^1(\tau) \frac{d\tau}{\tau}, \\ K_{\mathcal{E}_\rho}^{12} f^2(t) &= \int_0^\infty -\frac{\partial \mathcal{E}}{\partial y}(t - l \cos \theta, -l \sin \theta) f^2(l) dl = \int_0^\infty k_{\mathcal{E}_\rho}^{12} \left(\frac{t}{l}\right) f^2(l) \frac{dl}{l}. \end{aligned}$$

Similarly, we obtain the operators $K_{\mathcal{E}_\tau}^{\pm 11}$ and $K_{\mathcal{E}_\tau}^{12}$ and their corresponding kernels $k_{\mathcal{E}_\tau}^{\pm 11}$ and $k_{\mathcal{E}_\tau}^{12}$. The Mellin kernels obtained are given in the following kernel list.

$$(4-11) \quad \begin{array}{ccccc} \mathcal{E}(t - \tau, s - \rho) & k_{\mathcal{E}_\rho}^{\pm 11} & k_{\mathcal{E}_\tau}^{\pm 11} & k_{\mathcal{E}_\rho}^{12} & k_{\mathcal{E}_\tau}^{12} \\ \frac{1}{2\pi} \log((\tau - t)^2 + (\rho - s)^2) & \mp \delta & -h & k_0 + k_2 & -k_1 - k_3 \\ \frac{1}{\pi} \frac{(\tau - t)(\rho - s)}{(\tau - t)^2 + (\rho - s)^2} & -h & 0 & k_1 - k_3 & k_0 - k_2 \\ \frac{1}{\pi} \frac{(\tau - t)^2}{(\tau - t)^2 + (\rho - s)^2} & \pm \delta & 0 & -2k_2 & -2k_1 \\ \frac{1}{\pi} \frac{(\rho - s)^2}{(\tau - t)^2 + (\rho - s)^2} & \mp \delta & 0 & 2k_2 & 2k_1 \end{array}$$

In (4-11) we have used the notation δ and h for the distribution Mellin kernels $\delta(t - 1)$ and $\text{p.v. } \frac{1}{\pi} \frac{1}{t-1}$ respectively.

To show the explicit dependence of the kernels on the parameter $b = \frac{\lambda + \mu}{\lambda + 2\mu}$ (cf. (0-3)), we note the following “tricks” which follow from (0-3) and (0-14):

$$(4-12) \quad \begin{aligned} \mu m &= \frac{b}{2}, & \mu n &= 1 - \frac{b}{2}, & \mu(n + 2m) &= 1 + \frac{b}{2}, & \lambda(m - n) &= 1 - 2b, \\ \mu(2m - n) &= \frac{3}{2}b - 1, & \mu(n - m) &= 1 - b, & \mu(n + m) &= 1. \end{aligned}$$

We now give the structure of the operators $\mathbf{K}_T^{\pm 11}$ and $\mathbf{K}_N^{\pm 11}$.

Theorem 3. *Let*

$$(4-13) \quad \mathbf{K}_{T^0}^{11} = \begin{pmatrix} 0 & H \\ -H & 0 \end{pmatrix}.$$

Then

$$(4-14) \quad \begin{aligned} \mathbf{K}_T^{\pm 11} &= \pm \mathbf{I} + (1 - b)\mathbf{K}_{T^0}^{11}, \\ \mathbf{K}_N^{\pm 11} &= \pm \mathbf{I} + \frac{b}{2}\mathbf{K}_{T^0}^{11}. \end{aligned}$$

Proof. With $\vec{\nu} = -\mathbf{j}$, we have that

$$(4-15) \quad \mathbf{T}_{\vec{\nu}}(\mathbf{u}(\tau, \rho)) = - \begin{pmatrix} \mu u_{1,\rho} \\ \lambda u_{1,\tau} + (\lambda + 2\mu)u_{2,\rho} \end{pmatrix}.$$

We apply $\mathbf{T}_{\vec{\nu}(\tau, \rho)}$ to the columns of the fundamental matrix $\mathbf{\Gamma}(t - \tau, s - \rho)$ and take limits as $s \rightarrow 0^\pm$. As a sample calculation we calculate the kernel in

the 2, 1 position. Using the kernel list (4-11), we obtain

$$\begin{aligned}
 -k_{T,21}^{\pm 11} &= \lambda[n(-h) - m \cdot 0] + (\lambda + 2\mu)[-m(-h)] \\
 &= -h[\lambda n + (\lambda + 2\mu)(-m)] \\
 (4-16) \quad &= -h[\lambda(n - m) - 2\mu m] \\
 &= -h[2b - 1 - 2\frac{b}{2}] \\
 &= (1 - b)h.
 \end{aligned}$$

Similarly

$$(4-17) \quad -k_{N,21}^{\pm 11} = (\lambda + \mu)[n(-h) - m \cdot 0] + (\lambda + 2\mu)[-m(-h)].$$

The method of simplification to be consistently applied is to collect the coefficients of λ and μ and then to use the tricks (4-12) to write the coefficients in terms of b .

The remaining very tedious calculations are left to the reader. $\square$

To calculate the kernels in $\mathbf{K}_T^{12}$ and $\mathbf{K}_N^{12}$, we split the operators into

$$\mathbf{K}_T^{12} = \sin \theta \mathbf{K}_{T_i} - \cos \theta \mathbf{K}_{T_j},$$

where

$$\begin{aligned}
 \mathbf{K}_{T_i}^{12} \mathbf{f}^2(t) &= \int_0^\infty \mathbf{T}_i(\Gamma(t - l \cos \theta, -l \sin \theta)) \mathbf{f}^2(l) dl, \\
 (4-18) \quad \mathbf{K}_{T_j}^{12} \mathbf{f}^2(t) &= \int_0^\infty \mathbf{T}_j(\Gamma(t - l \cos \theta, -l \sin \theta)) \mathbf{f}^2(l) dl,
 \end{aligned}$$

and

$$\begin{aligned}
 \mathbf{K}_{N_i}^{12} \mathbf{f}^2(t) &= \int_0^\infty \mathbf{N}_i(\Gamma(t - l \cos \theta, -l \sin \theta)) \mathbf{f}^2(l) dl, \\
 (4-19) \quad \mathbf{K}_{N_j}^{12} \mathbf{f}^2(t) &= \int_0^\infty \mathbf{N}_j(\Gamma(t - l \cos \theta, -l \sin \theta)) \mathbf{f}^2(l) dl.
 \end{aligned}$$

Note that the (-1) from the orientation has been omitted in the definitions (4-18) and (4-19).

Theorem 4. *The operators in (4-18) and (4-19) have the following structure:*

$$\begin{aligned}
 \mathbf{K}_{T_i}^{12} &= \mathbf{K}_{T_i^0}^{12} + b \mathbf{K}_{i^b}, & \mathbf{K}_{T_j}^{12} &= \mathbf{K}_{T_j^0}^{12} + b \mathbf{K}_{j^b}, \\
 (4-20) \quad \mathbf{K}_{N_i}^{12} &= \mathbf{K}_{N_i^0}^{12} + \frac{b}{2} \mathbf{K}_{i^b}, & \mathbf{K}_{N_j}^{12} &= \mathbf{K}_{N_j^0}^{12} + \frac{b}{2} \mathbf{K}_{j^b},
 \end{aligned}$$

where the Hardy kernels are

$$\begin{aligned}
 \mathbf{K}_{\mathbf{T}_i^0}^{12} &= \begin{pmatrix} -k_1 - k_3 & -k_0 - k_2 \\ k_0 + k_2 & -k_1 - k_3 \end{pmatrix}, \\
 \mathbf{K}_{\mathbf{T}^b}^{12} &= \begin{pmatrix} k_1 - k_3 & k_0 + 3k_2 \\ -k_0 + k_2 & -k_1 + k_3 \end{pmatrix}, \\
 \mathbf{K}_{\mathbf{N}_i^0}^{12} &= \begin{pmatrix} -k_1 - k_3 & 0 \\ 0 & -k_1 - k_3 \end{pmatrix}, \\
 \mathbf{K}_{\mathbf{T}_j^0}^{12} &= \begin{pmatrix} k_0 + k_2 & -k_1 - k_3 \\ k_1 + k_3 & k_0 + k_2 \end{pmatrix}, \\
 \mathbf{K}_{\mathbf{J}^b}^{12} &= \begin{pmatrix} -k_0 + k_2 & -k_1 + k_3 \\ -3k_1 - k_3 & k_0 - k_2 \end{pmatrix}, \\
 \mathbf{K}_{\mathbf{N}_j^0}^{12} &= \begin{pmatrix} k_0 + k_2 & 0 \\ 0 & k_0 + k_2 \end{pmatrix}.
 \end{aligned}
 \tag{4-21}$$

Proof. A typical computation is for the kernel in the 1, 1 position.

$$\begin{aligned}
 k_{\mathbf{T}_i, 11}^{12} &= (\lambda + 2\mu)[n(-k_1 - k_3) - m(-2k_1)] + \lambda(-m)(k_1 - k_3) \\
 &= k_1[(\lambda + 2\mu)(-n + 2m) - \lambda m] + k_3[(\lambda + 2\mu)(-n) + \lambda m].
 \end{aligned}
 \tag{4-22}$$

To simplify the coefficients of k_1 and k_3 , collect the coefficients of λ and μ , and apply the tricks (4-12) to obtain

$$k_{\mathbf{T}_i, 11}^{12} = k_1(-1 + b) + k_3(-1 - b).$$

In calculating the remaining kernels, note that the coefficients to be calculated for $k_{\mathbf{T}_j, rs}^{12}$ are the negatives of the coefficients calculated for $k_{\mathbf{T}_i, sr}^{12}$.

Again the very tedious details are left to the reader. $\square$

Taking into account the (-1) introduced by the orientation of the ray S_2 , we have

$$\begin{aligned}
 \mathbf{K}_{\mathbf{T}}^{12} &= \sin \theta \mathbf{K}_{\mathbf{T}_i}^{12} - \cos \theta \mathbf{K}_{\mathbf{T}_j}^{12}, \\
 \mathbf{K}_{\mathbf{N}}^{12} &= \sin \theta \mathbf{K}_{\mathbf{N}_i}^{12} - \cos \theta \mathbf{K}_{\mathbf{N}_j}^{12}.
 \end{aligned}
 \tag{4-23}$$

We introduce

$$\begin{aligned}
 \mathbf{K}_{\mathbf{T}^0}^{12} &= \sin \theta \mathbf{K}_{\mathbf{T}_i^0}^{12} - \cos \theta \mathbf{K}_{\mathbf{T}_j^0}^{12}, \\
 \mathbf{K}_{\mathbf{N}^0}^{12} &= \sin \theta \mathbf{K}_{\mathbf{N}_i^0}^{12} - \cos \theta \mathbf{K}_{\mathbf{N}_j^0}^{12}, \\
 \mathbf{K}_{\mathbf{J}^b}^{12} &= \sin \theta \mathbf{K}_{\mathbf{I}^b}^{12} - \cos \theta \mathbf{K}_{\mathbf{J}^b}^{12},
 \end{aligned}
 \tag{4-24}$$

so that

$$\begin{aligned}
 \mathbf{K}_{\mathbf{T}}^{12} &= \mathbf{K}_{\mathbf{T}^0}^{12} + b \mathbf{K}_{\mathbf{J}^b}^{12}, \\
 \mathbf{K}_{\mathbf{N}}^{12} &= \mathbf{K}_{\mathbf{N}^0}^{12} + \frac{b}{2} \mathbf{K}_{\mathbf{J}^b}^{12}.
 \end{aligned}
 \tag{4-25}$$

Next we calculate $\mathbf{K}_{\{\cdot\}}^{21}$ and $\mathbf{K}_{\{\cdot\}}^{22}$.

Let U be the reflection about the ray $\{(t, s) = (l \cos \frac{\theta}{2}, l \sin \frac{\theta}{2}) : l > 0\}$:

$$(4-26) \quad U = \begin{pmatrix} \cos \theta & \sin \theta \\ \sin \theta & -\cos \theta \end{pmatrix}.$$

Note that $UU = I_2$ and that $\det U = -1$.

Then it is "obvious" geometrically or may be verified by a calculation that

$$(4-27) \quad \begin{aligned} \mathbf{K}_T^{21} &= U \mathbf{K}_T^{12} U, & \mathbf{K}_T^{\pm 22} &= U \mathbf{K}_T^{\pm 11} U, \\ \mathbf{K}_N^{21} &= U \mathbf{K}_N^{12} U, & \mathbf{K}_N^{\pm 22} &= U \mathbf{K}_N^{\pm 11} U. \end{aligned}$$

Hence both $\mathbf{K}_T^\pm$ and $\mathbf{K}_N^\pm$ have the structure

$$(4-28) \quad \mathbf{K}_{\{\cdot\}}^\pm = \begin{pmatrix} \mathbf{K}_{\{\cdot\}}^{\pm 11} & \mathbf{K}_{\{\cdot\}}^{12} \\ U \mathbf{K}_{\{\cdot\}}^{12} U & U \mathbf{K}_{\{\cdot\}}^{\pm 11} U \end{pmatrix}.$$

We let $\hat{U}$ be the 4×4 matrix

$$(4-29) \quad \hat{U} = \begin{pmatrix} I_2 & 0 \\ 0 & U \end{pmatrix}.$$

Then

$$(4-30) \quad \hat{U} \mathbf{K}_{\{\cdot\}}^\pm \hat{U} = \begin{pmatrix} \mathbf{K}_{\{\cdot\}}^{\pm 11} & \mathbf{K}_{\{\cdot\}}^{12} U \\ \mathbf{K}_{\{\cdot\}}^{12} U & \mathbf{K}_{\{\cdot\}}^{\pm 11} \end{pmatrix}.$$

5. THE SYMBOLS IN A PLANE SECTOR

We are now reduced to calculating the determinant of a matrix of Mellin symbols of the form

$$(5-1) \quad \text{Smb}l^{\frac{1}{p}}(\hat{U} \mathbf{K}_{\{\cdot\}}^\pm \hat{U}) = \begin{pmatrix} \tilde{\mathbf{K}}_{\{\cdot\}}^{\pm 11} & \tilde{\mathbf{K}}_{\{\cdot\}}^{12} U \\ \tilde{\mathbf{K}}_{\{\cdot\}}^{12} U & \tilde{\mathbf{K}}_{\{\cdot\}}^{\pm 11} \end{pmatrix}.$$

First we note that if A and B are 2×2 matrices, then

$$(5-2) \quad \det \begin{pmatrix} A & B \\ B & A \end{pmatrix} = \det(A - B) \cdot \det(A + B).$$

Our goal is to express $\det(\tilde{\mathbf{K}}_{\{\cdot\}}^{\pm 11} \pm \tilde{\mathbf{K}}_{\{\cdot\}}^{12} U)$ as the difference of two squares so that the zeroes can easily be found.

We shall call *antireflective* a matrix of the form $C = \begin{pmatrix} c_{11} & c_{12} \\ -c_{12} & c_{11} \end{pmatrix}$; note that $\det C = c_{11}^2 + c_{12}^2$. We shall call *reflective* a matrix of the form $D = \begin{pmatrix} d_{11} & d_{12} \\ d_{12} & -d_{11} \end{pmatrix}$; note that $\det D = -(d_{11}^2 + d_{12}^2)$. Finally observe that if C is antireflective and D is reflective, then

$$(5-3) \quad \det(C \pm D) = (c_{11}^2 + c_{12}^2) - (d_{11}^2 + d_{12}^2) = \det C + \det D.$$

First we record the structure of $\text{Smb}l^{\frac{1}{p}}(\mathbf{K}_{\{\cdot\}}^{\pm 11})$ near $t = 0$. If $\mathbf{K}_T^{11}$ is as defined in (4-13), it is immediate that near $t = 0$,

$$(5-4) \quad \sin \pi z \text{Smb}l^{\frac{1}{p}}(\mathbf{K}_T^{11})(t, z) = \begin{pmatrix} 0 & -\cos \pi z \\ \cos \pi z & 0 \end{pmatrix};$$

the matrix in (5-4) is antireflective.

Theorem 5. Near $t = 0$, the matrices $\text{Smb}l^{\frac{1}{p}}(\mathbf{K}_{\{\cdot\}}^{\pm 11})$ are antireflective; the symbols are given by

$$(5-5) \quad \begin{aligned} \sin \pi z \text{Smb}l^{\frac{1}{p}}(\mathbf{K}_{\mathbf{T}}^{\pm 11})(t, z) &= \begin{pmatrix} \pm \sin \pi z & -(1-b)\cos \pi z \\ (1-b)\cos \pi z & \pm \sin \pi z \end{pmatrix}, \\ \sin \pi z \text{Smb}l^{\frac{1}{p}}(\mathbf{K}_{\mathbf{N}}^{\pm 11})(t, z) &= \begin{pmatrix} \pm \sin \pi z & -\frac{b}{2}\cos \pi z \\ \frac{b}{2}\cos \pi z & \pm \sin \pi z \end{pmatrix}. \end{aligned}$$

To calculate the symbols of the Hardy kernel operators in (4-21), we give the Mellin transforms of the kernels. First we introduce

$$(5-6) \quad \begin{aligned} C_{\theta}(z) &= \cos((\pi - \theta)z + \theta), \\ S_{\theta}(z) &= \sin((\pi - \theta)z + \theta). \end{aligned}$$

We list the following table of Mellin transforms for the kernels $k_j(t)$ defined by (4-6):

$$(5-7) \quad \begin{aligned} \sin \pi z \tilde{k}_0(z) &= \frac{1}{2}\{(-z+2)\sin \theta C_{\theta}(z-1) - \cos \theta S_{\theta}(z-1)\}, \\ \sin \pi z \tilde{k}_1(z) &= -\frac{1}{2}\{(z-1)\sin \theta S_{\theta}(z-1)\}, \\ \sin \pi z \tilde{k}_2(z) &= \frac{1}{2}\{z\sin \theta C_{\theta}(z-1) - \cos \theta S_{\theta}(z-1)\}, \\ \sin \pi z \tilde{k}_3(z) &= \frac{1}{2}\{(z+1)\sin \theta S_{\theta}(z-1) + 2\cos \theta C_{\theta}(z-1)\}. \end{aligned}$$

For obvious reasons we note the following formulas which follow easily from (5-7) and the trigonometric addition formulas.

$$(5-8) \quad \begin{aligned} \sin \pi z(\tilde{k}_0(z) - \tilde{k}_2(z)) &= (-z+1)\sin \theta C_{\theta}(z-1), \\ \sin \pi z(\tilde{k}_1(z) - \tilde{k}_3(z)) &= -z\sin \theta S_{\theta}(z-1) - \cos \theta C_{\theta}(z-1), \\ \sin \pi z(\tilde{k}_0(z) + 3\tilde{k}_2(z)) &= (z+1)\sin \theta C_{\theta}(z-1) - 2\cos \theta S_{\theta}(z-1), \\ \sin \pi z(3\tilde{k}_1(z) - \tilde{k}_3(z)) &= (-z+2)\sin \theta S_{\theta}(z-1) + \cos \theta C_{\theta}(z-1), \\ \sin \pi z(\tilde{k}_0(z) + \tilde{k}_2(z)) &= \sin \theta C_{\theta}(z-1) - \cos \theta C_{\theta}(z-1) \\ &= -\sin((\pi - \theta)(z-1)), \\ \sin \pi z(\tilde{k}_1(z) + \tilde{k}_3(z)) &= \cos \theta C_{\theta}(z-1) + \sin \theta S_{\theta}(z-1) \\ &= \cos((\pi - \theta)(z-1)). \end{aligned}$$

The structure of the symbols of the operators (4-24) is explained in Theorem 6. We first introduce the reflective matrix

$$(5-8) \quad V = \begin{pmatrix} \sin \theta & -\cos \theta \\ -\cos \theta & -\sin \theta \end{pmatrix}.$$

Theorem 6. The symbols of the operators $\mathbf{K}_{\mathbf{T}^0}^{12}U$ and $\mathbf{K}_{\mathbf{N}^0}^{12}U$ are reflective matrices and satisfy

$$(5-10) \quad \begin{aligned} \sin \pi z \text{Smb}l^{\frac{1}{p}}(\mathbf{K}_{\mathbf{T}^0}^{12}U)(t, z) &= \begin{pmatrix} \sin(\pi - \theta)(z-1) & -\cos(\pi - \theta)(z-1) \\ -\cos(\pi - \theta)(z-1) & -\sin(\pi - \theta)(z-1) \end{pmatrix}, \\ &= -\sin(\pi - \theta)zU - \cos(\pi - \theta)zV, \\ \sin \pi z \text{Smb}l^{\frac{1}{p}}(\mathbf{K}_{\mathbf{N}^0}^{12}U)(t, z) &= -\sin(\pi - \theta)zU. \end{aligned}$$

The symbol of the operator $\mathbf{K}_{\nu^b}^{12}$ is a matrix of the form $\{z \times \text{antireflective} + \text{reflective}\}$ and satisfies

$$(5-11) \quad \sin \pi z \text{Smb}l_{\nu^b}^{\frac{1}{p}}(\mathbf{K}_{\nu^b}^{12}U)(t, z) = z \sin \theta \begin{pmatrix} \cos(\pi - \theta)z & -\sin(\pi - \theta)z \\ \sin(\pi - \theta)z & \cos(\pi - \theta)z \end{pmatrix} + \cos(\pi - \theta)zV.$$

Finally we are ready to calculate $\det(\tilde{\mathbf{K}}_{\{\cdot\}}^{\pm 11} \pm \tilde{\mathbf{K}}_{\{\cdot\}}^{12}U)$. To avoid further confusion, we now calculate $\det \text{Smb}l_{\nu^b}^{\frac{1}{p}}(\mathbf{K}_{\{\cdot\}}^+)$.

Define

$$(5-12) \quad \begin{aligned} f_{\mathbf{T}}^{\oplus \pm}(z) &= \det(\sin \pi z(\tilde{\mathbf{K}}_{\mathbf{T}}^{\pm 11} \pm \tilde{\mathbf{K}}_{\mathbf{T}}^{12}U)), \\ f_{\mathbf{N}}^{\oplus \pm}(z) &= \det(\sin \pi z(\tilde{\mathbf{K}}_{\mathbf{N}}^{\pm 11} \pm \tilde{\mathbf{K}}_{\mathbf{N}}^{12}U)). \end{aligned}$$

Next define

$$(5-13) \quad \begin{aligned} g_{\mathbf{T}}^{++}(z) &= bz \sin \theta + (2 - b) \sin(2\pi - \theta)z \\ &= -bz \sin(2\pi - \theta) + (2 - b) \sin(2\pi - \theta)z, \\ g_{\mathbf{T}}^{--}(z) &= bz \sin \theta - (2 - b) \sin(2\pi - \theta)z \\ &= -bz \sin(2\pi - \theta) - (2 - b) \sin(2\pi - \theta)z, \\ g_{\mathbf{T}}^{+-} &= b(z \sin \theta + \sin \theta z), \\ g_{\mathbf{T}}^{-+} &= b(z \sin \theta - \sin \theta z). \end{aligned}$$

Let

$$(5-14) \quad \begin{aligned} g_{\mathbf{N}}^{++}(z) &= \frac{b}{2}z \sin \theta + \left(1 - \frac{b}{2}\right) \sin(2\pi - \theta)z \\ &= -\frac{b}{2}z \sin(2\pi - \theta) + \left(1 - \frac{b}{2}\right) \sin(2\pi - \theta)z, \\ g_{\mathbf{N}}^{--}(z) &= \frac{b}{2}z \sin \theta - \left(1 - \frac{b}{2}\right) \sin(2\pi - \theta)z \\ &= -\frac{b}{2}z \sin \theta - \left(1 - \frac{b}{2}\right) \sin(2\pi - \theta)z, \\ g_{\mathbf{N}}^{+-} &= \frac{b}{2}z \sin \theta + \left(1 + \frac{b}{2}\right) \sin \theta z, \\ g_{\mathbf{N}}^{-+} &= \frac{b}{2}z \sin \theta - \left(1 + \frac{b}{2}\right) \sin \theta z. \end{aligned}$$

Theorem 7. We have that

$$(5-15) \quad \begin{aligned} f_{\mathbf{T}}^{\oplus \pm}(z) &= g_{\mathbf{T}}^{\pm+}(z) \cdot g_{\mathbf{T}}^{\pm-}(z), \\ f_{\mathbf{N}}^{\oplus \pm}(z) &= g_{\mathbf{N}}^{\pm+}(z) \cdot g_{\mathbf{N}}^{\pm-}(z). \end{aligned}$$

Proof. Let

$$(5-16) \quad A^{\pm} = \sin \pi z(\tilde{\mathbf{K}}_{\mathbf{T}}^{\pm 11} \pm \tilde{\mathbf{K}}_{\mathbf{T}}^{12}U).$$

Using (4-25), (5-10), and (5-11), the antireflective part of $A^\pm$ is
(5-17)

$$A_{\text{anti}}^\pm = \sin \pi z (\mathbf{I}_2 + (1-b)\tilde{\mathbf{K}}_{\mathbf{T}^0}^{11}) \pm z(\sin \theta) \begin{pmatrix} \cos(\pi - \theta)z & -\sin(\pi - \theta)z \\ \sin(\pi - \theta)z & \cos(\pi - \theta)z \end{pmatrix},$$

which has determinant given by

$$(5-18) \quad (\sin \pi z \pm bz \sin \theta \cos(\pi - \theta)z)^2 + ((1-b)\cos \pi z \pm bz \sin \theta \sin(\pi - \theta)z)^2.$$

From (4-25) and (5-11), the reflective part of $A^\pm$ is

$$(5-19) \quad A_{\text{refl}}^\pm = \pm(\tilde{\mathbf{K}}_{\mathbf{T}^0}^{12}U + b \cos(\pi - \theta)z V),$$

which has determinant given by

$$(5-20) \quad \begin{aligned} & - \left[(\cos \theta \sin(\pi - \theta)z + (1-b) \sin \theta \cos(\pi - \theta)z)^2 \right. \\ & \quad \left. + (\sin \theta \sin(\pi - \theta)z - (1-b) \cos \theta \cos(\pi - \theta)z)^2 \right] \\ & = -[\sin^2(\pi - \theta)z + (1-b)^2 \cos^2(\pi - \theta)z]. \end{aligned}$$

Thus

$$(5-21) \quad \begin{aligned} f_{\mathbf{T}}^{\oplus\pm}(z) = & \{\sin^2 \pi z - \sin^2(\pi - \theta)z\} + (1-b)^2 \{\cos^2 \pi z - \cos^2(\pi - \theta)z\} \\ & + b^2 z^2 \sin^2 \theta \pm 2bz \sin \theta \{\sin \pi z \cos(\pi - \theta)z \\ & \quad + (1-b) \cos \pi z \sin(\pi - \theta)z\}. \end{aligned}$$

In the last two terms of (5-21) we complete the square to obtain

$$(5-22) \quad f_{\mathbf{T}}^{\oplus\pm}(z) = (bz \sin \theta \pm (\sin \pi z \cos(\pi - \theta)z + (1-b)\cos \pi z \sin(\pi - \theta)z))^2 + \text{rest},$$

where

$$(5-23) \quad \begin{aligned} \text{rest} = & \sin^2 \pi z - \sin^2(\pi - \theta)z + (1-b)^2 [\cos^2 \pi z - \cos^2(\pi - \theta)z] \\ & - (\sin \pi z \cos(\pi - \theta)z + (1-b)\cos \pi z \sin(\pi - \theta)z)^2 \\ = & -2(1-b) \sin \pi z \cos(\pi - \theta)z \cos \pi z \sin(\pi - \theta)z \\ & + \{\sin^2 \pi z - \sin^2(\pi - \theta)z - \sin^2 \pi z \cos^2(\pi - \theta)z\} \\ & + (1-b)^2 \{\cos^2 \pi z - \cos^2(\pi - \theta)z - \cos^2 \pi z \sin^2(\pi - \theta)z\}. \end{aligned}$$

The two terms in $\{\cdot\}$ simplify respectively to $-\cos^2 \pi z \sin^2(\pi - \theta)z$ and $-\sin^2 \pi z \cos^2(\pi - \theta)z$ so that

$$(5-24) \quad \text{rest} = -\{\cos \pi z \sin(\pi - \theta)z + (1-b) \sin \pi z \cos(\pi - \theta)z\}^2.$$

From (5-22) and (5-24), the function $f_{\mathbf{T}}^{\oplus\pm}$ has been written as the difference of two squares $\alpha^2 - \beta^2$ so that of course $f_{\mathbf{T}}^{\oplus\pm} = (\alpha + \beta)(\alpha - \beta)$. That the terms have the form given by (5-15) follows from the addition formulas.

The explicit calculations for $f_{\mathbf{N}}^{\oplus\pm}$ proceed in a like manner. $\square$

Remark. In a similar manner we may calculate

$$(5-25) \quad \begin{aligned} f_{\mathbf{T}}^{\ominus\pm}(z) &= \det(\sin \pi z (\tilde{\mathbf{K}}_{\mathbf{T}}^{-11} \pm \tilde{\mathbf{K}}_{\mathbf{T}}^{12} U)), \\ f_{\mathbf{N}}^{\ominus\pm}(z) &= \det(\sin \pi z (\tilde{\mathbf{K}}_{\mathbf{N}}^{-11} \pm \tilde{\mathbf{K}}_{\mathbf{N}}^{12} U)). \end{aligned}$$

In the calculation the determinant of the reflective part is unchanged and for the determinant of the antireflective part (5-18) is replaced by

$$(5-26) \quad (-\sin \pi z \pm bz \sin \theta \cos(\pi - \theta)z)^2 + ((1 - b)\cos \pi z \pm bz \sin \theta \sin(\pi - \theta)z)^2.$$

The final result is that

$$(5-27) \quad \begin{aligned} \det(\sin \pi z \text{Smb}l^{\frac{1}{p}}(\mathbf{K}_{\mathbf{T}}^-)) &= (bz \sin \theta - b \sin(2\pi - \theta)z)(bz \sin \theta - (2 - b) \sin \theta z) \\ &\quad \times (bz \sin \theta + b \sin(2\pi - \theta)z)(bz \sin \theta + (2 - b) \sin \theta z). \end{aligned}$$

As expected, $\det(\sin \pi z \text{Smb}l^{\frac{1}{p}}(\mathbf{K}_{\mathbf{T}}^-))$ has the same form as

$$\det(\sin \pi z \text{Smb}l^{\frac{1}{p}}(\mathbf{K}_{\mathbf{T}}^+)),$$

with the roles of θ and $2\pi - \theta$ interchanged, since $2\pi - \theta$ is the “interior” angle for the complement of Ω^+ .

6. THE SINGULARITIES OF THE PRINCIPAL SYMBOL

The zeroes and change in argument of $\det(\text{Smb}l^{\frac{1}{p}}(\mathbf{K}_{\{\cdot\}}^+)) = (\sin \pi z)^{-4} f_{\{\cdot\}}^{\oplus+}(z) \cdot f_{\{\cdot\}}^{\oplus-}(z)$ can be easily calculated from (5-15). Essentially we must consider functions of the form

$$(6-1) \quad g_{\alpha, \gamma}(z) = \frac{\sin \gamma z}{\gamma z} - \alpha \frac{\sin \gamma}{\gamma},$$

where $-1 \leq \alpha \leq 1$ and $0 < \gamma < 2\pi$. An interesting discussion of all the complex zeroes of (6-1) is given in Vasilopoulos [V] or Karal and Karp [KK]. Let $g(Z) = \sin Z/Z$; of course $g(Z)$ has simple zeroes at $Z = \pm n\pi$, $n = 1, 2, \dots$. The next lemma is a summary of the remarks of [V, pp. 57 ff.] and is proved using the Argument Principle.

Lemma 6.1. *Let $0 < C < 1$. Then the equation*

$$(6-2) \quad g(Z) - C = 0$$

has exactly one root in the strip $\Gamma_{0, \pi}$, has no roots in the strips $\Gamma_{(2n-1)\pi, 2n\pi}$, $n = 1, 2, \dots$, and has exactly two roots in the strips $\Gamma_{2n\pi, (2n+1)\pi}$, $n = 1, 2, \dots$.

The equation

$$(6-3) \quad g(Z) + C = 0$$

has no roots in the strips $\Gamma_{(2n-2)\pi, (2n-1)\pi}$, $n = 1, 2, \dots$, and has exactly two roots in the strips $\Gamma_{(2n-1)\pi, 2n\pi}$, $n = 1, 2, \dots$.

Proof. The lemma follows from calculating the change in argument of $g(Z) \pm C$ on the contours $\Gamma_{n\pi} = \{Z = n\pi + iY : -\infty < Y < +\infty\}$. Let

$$g_n(Y) = g(n\pi + iY) = (-1)^n \frac{(Y + n\pi i) \sinh(\pi Y)}{n^2 \pi^2 + Y^2}.$$

The change in argument of $g_0(Y) \pm C$ is 0; the change in argument of $g_{2k-1}(Y) - C$ is 0 and the change in argument of $g_{2k}(Y) - C$ is -2π ; in contrast, the change in argument of $g_{2k}(Y) + C$ is 0 and the change in argument of $g_{2k-1}(Y) + C$ has change in argument -2π . Taking into account the change in argument of $g(X \pm i\infty) \pm C$, the Argument Principle gives the lemma. $\square$

We denote by γ_{crit} the point where the minimum value of $g(t)$ on $[0, 2\pi]$ occurs; $\tan \gamma_{\text{crit}} = \gamma_{\text{crit}}$; $\gamma_{\text{crit}} \approx 257^\circ 27'$.

Lemma 6.2. *Consider the equation*

$$(6-4) \quad g_{\alpha, \gamma}(z) = \frac{\sin \gamma z}{\gamma z} - \alpha \frac{\sin \gamma}{\gamma} = 0, \quad z \in \Gamma_{0,1}.$$

- (1) Let $\alpha = 1$. For $0 < \gamma \leq \gamma_{\text{crit}}$, the equation (6-4) has no roots in $\Gamma_{0,1}$; for $\gamma_{\text{crit}} < \gamma < 2\pi$ there is a single root $z_0(1, \gamma) \in \Gamma_{0,1}$ which decreases monotonically from 1 to $\frac{1}{2}$ as γ increases from γ_{crit} to 2π .
- (2) Let $-1 \leq \alpha < 1$. For $0 < \gamma \leq \pi$, the equation (6-4) has no roots in $\Gamma_{0,1}$; for $\pi < \gamma < 2\pi$ there is a single root $z_0(\alpha, \gamma) \in \Gamma_{0,1}$ which, for fixed α , decreases monotonically from 1 to $\frac{1}{2}$ as γ increases from π to 2π .

Proof. The stated roots are understood easily by sketching the graph of g on $[0, 2\pi]$. That there are no complex roots follows from Lemma 5.1. $\square$

We are now ready to announce the zeroes of $\det(\text{Smb}l^{\frac{1}{p}}(\mathbf{K}_T^+))$. First observe that if $b = 0$, we have that g_T^{+-} and g_T^{-+} are identically 0; in particular $\text{Smb}l^{\frac{1}{p}}(\mathbf{K}_T^+)(\frac{1}{p} \pm i\infty)$ has rank 2; this shows that the boundary operator $\mathbf{T}(\mathbf{u})\vec{\nu}$ does not cover L . The following theorem summarizes the roots of $\det(\text{Smb}l^{\frac{1}{p}}(\mathbf{K}_T^+)) = 0$ in $\Gamma_{0,1}$.

Theorem 8. (1) For $t = 0$:

$$(6-5) \quad \det(\text{Smb}l^{\frac{1}{p}} \mathbf{K}_{\{\cdot\}}^+) = \frac{1}{\sin^4 \pi z} g_{\{\cdot\}}^{++}(z) g_{\{\cdot\}}^{+-}(z) g_{\{\cdot\}}^{-+}(z) g_{\{\cdot\}}^{--}(z).$$

- (2) The equations $g_T^{++} = 0$ and $g_N^{--} = 0$ have roots where

$$(6-6) \quad \frac{\sin(2\pi - \theta)z}{2\pi - \theta} = \frac{b}{2-b} \frac{\sin(2\pi - \theta)}{2\pi - \theta};$$

Equation (6-6) has a root z_0 in $\Gamma_{0,1}$ for $0 < \theta < \pi$ ($0 \leq b < 1$), or for only $0 < \theta < 2\pi - \gamma_{\text{crit}}$ ($b = 1$).

- (3) The equations $g_T^{--} = 0$ and $g_N^{++} = 0$ have roots where

$$(6-7) \quad \frac{\sin(2\pi - \theta)z}{(2\pi - \theta)z} = -\frac{b}{2-b} \frac{\sin(2\pi - \theta)}{2\pi - \theta}.$$

Equation (6-7) has a root z_0 in $\Gamma_{0,1}$ for $0 < \theta < \pi$ ($0 \leq b \leq 1$).

(4) The equation $g_T^{+-} = 0$ has a root where

$$(6-8) \quad \frac{\sin \theta z}{\theta z} = -\frac{\sin \theta}{\theta}.$$

Equation (6-8) has a root z_0 in $\Gamma_{0,1}$ iff $\pi < \theta < 2\pi$.

(5) The equation $g_T^{-+} = 0$ has a root where

$$(6-9) \quad \frac{\sin \theta z}{\theta z} = \frac{\sin \theta}{\theta}.$$

Equation (6-9) has a root z_0 in $\Gamma_{0,1}$ iff $2\pi - \gamma_{\text{crit}} < \theta < 2\pi$.

(6) The equation $g_N^{+-} = 0$ has a root where

$$(6-10) \quad \frac{\sin \theta z}{\theta z} = -\frac{b}{2+b} \frac{\sin \theta}{\theta}.$$

Equation (6-10) has a root z_0 in $\Gamma_{0,1}$ iff $\pi < \theta < 2\pi$.

(7) The equation $g_N^{-+} = 0$ has a root where

$$(6-11) \quad \frac{\sin \theta z}{\theta z} = \frac{b}{2+b} \frac{\sin \theta}{\theta}.$$

Equation (6-11) has a root z_0 in $\Gamma_{0,1}$ iff $\pi < \theta < 2\pi$.

(8) If $0 < b \leq 1$, for $0 < \frac{1}{p} \leq \frac{1}{2}$ the change in argument of $\det(\text{Smb}l^{\frac{1}{p}} \mathbf{K}_{\{\cdot\}}^+)$ on the contour $\Gamma_{\frac{1}{p}}$ is 0.

(9) If $0 < b \leq 1$, when $\theta = \pi$, for $0 < \frac{1}{p} < 1$ the change in argument of $\det(\text{Smb}l^{\frac{1}{p}} \mathbf{K}_{\{\cdot\}}^+)$ on the contour $\Gamma_{\frac{1}{p}}$ is 0.

Proof. Statement (1) is Theorem 6; statements (2)–(7) follow from Lemma 5.2. Statements (8) and (9) are proved by calculating the change in argument near $\frac{1}{p} = 0$ and the Argument Principle. $\square$

Remark. At the zeroes of $\det(\text{Smb}l^{\frac{1}{p}} \mathbf{K}_{\{\cdot\}}^+)$ the eigenvectors of the the 2×2 matrices $A^{\pm}$ are easily computed; in turn the eigenvectors of $\hat{U} \hat{\mathbf{K}}_{\{\cdot\}}^+ \hat{U}$ and $\hat{\mathbf{K}}_{\{\cdot\}}^+$ are calculated.

Definition 6.1. With $\mathbf{K}_{\{\cdot\}}^{\pm}$ as in equation (4-28), for $\frac{1}{p}$ not a zero of $\det(\sin \pi z \text{Smb}l^{\frac{1}{p}}(\mathbf{K}_{\{\cdot\}}^{\pm}))$, define

$$(6-12) \quad I_{\{\cdot\}}^{\pm}(\frac{1}{p}, b, \theta) = [\text{number of zeroes of } \det(\sin \pi z \text{Smb}l^{\frac{1}{p}}(\mathbf{K}_{\{\cdot\}}^{\pm})) \text{ in } (0, \frac{1}{p})].$$

We note the following facts about $I_{\{\cdot\}}^{\pm}(\frac{1}{p}, b, \theta)$.

$$(1) \quad I_{\{\cdot\}}^{\pm}(\frac{1}{p}, b, \theta) = \frac{1}{2\pi} (\text{change in arg of } \det \hat{\mathbf{K}}_{\{\cdot\}}^{\pm} \text{ on } \Gamma_{\frac{1}{p}}).$$

$$(2) \quad I_{\{\cdot\}}^+(\frac{1}{p}, b, \theta) = I_{\{\cdot\}}^-(\frac{1}{p}, b, 2\pi - \theta).$$

$$(3) \quad \text{For } 0 < \theta < \pi, \quad I_T^+(\frac{1}{p}, b, \theta) = I_N^+(\frac{1}{p}, b, \theta).$$

$$(4) \quad \text{For } \pi < \theta < 2\pi, \quad I_T^+(\frac{1}{p}, b, \theta) = I_T^-(\frac{1}{p}, b, 2\pi - \theta) \text{ is independent of } b \text{ for } 0 < b \leq 1.$$

Let us now return to the problem on the domain Ω^+ as described in §4. For $\mathbf{f} \in L^p(\partial\Omega^+)$, let

$$(6-13) \quad \mathbf{K}_T^\pm \mathbf{f}(P) = \pm \mathbf{I}\mathbf{f}(P) + \text{p.v.} \int_{\partial\Omega^+} \mathbf{T}_{\vec{\nu}(Q)}(\Gamma(X - Q))\mathbf{f}(Q) d\sigma_Q,$$

$$(6-14) \quad \mathbf{K}_T^\pm \mathbf{f}(P) = \pm \mathbf{I}\mathbf{f}(P) + \text{p.v.} \int_{\partial\Omega^+} \mathbf{N}_{\vec{\nu}(Q)}(\Gamma(X - Q))\mathbf{f}(Q) d\sigma_Q.$$

When (6-13) or (6-14) is written as a big $4N \times 4N$ system of Mellin operators as in (3-1) ff., the operators $K^{(2i)}$ of (3-3) correspond to the operator $\mathbf{K}_{\{\cdot\}}^\pm$ of (4-28) with $\theta = \theta_{2i}$; the operators $K^{(2i-1)}$ of (3-3) correspond to the operator $\mathbf{K}_{\{\cdot\}}^\pm$ of (4-28) with $\theta = \pi$. Using Theorem 2, Theorem 7, and Theorem 8, we obtain

Theorem 9. Let $\mathbf{K}_{\{\cdot\}}^\pm$ denote one of the operators (6-13) or (6-14). Then

- (1) For $1 < p < \infty$, $\mathbf{K}_{\{\cdot\}}^\pm$ is a Fredholm operator on $L^p(\partial\Omega^+)$ iff for all j , $j = 1, \dots, N$, the operators (4-28), with $\theta = \theta_{2j}$, is a Fredholm operator on $[L^p(\mathbf{R}^+)]^4$.
- (2) If $b = 0$, $\mathbf{K}_T^\pm$ is not a Fredholm operator on $L^p(\partial\Omega^+)$ for any p , $1 < p < \infty$.
- (3) If $b = 0$, $\mathbf{K}_N^\pm$ is not a Fredholm operator on $L^p(\partial\Omega^+)$ iff for some j , $j = 1, \dots, N$, $\sin(\theta_{2j}\frac{1}{p}) = 0$ or $\sin((2\pi - \theta_{2j})\frac{1}{p}) = 0$.
- (4) If $0 < b \leq 1$, $\mathbf{K}_{\{\cdot\}}^\pm$ is a Fredholm operator on $L^p(\partial\Omega^+)$ for all p , $2 \leq p < \infty$.
- (5) If $0 < b \leq 1$, the "bad values" of p in (1, 2), for which the operators $\mathbf{K}_{\{\cdot\}}^\pm$ are not Fredholm on $L^p(\partial\Omega^+)$ form a discrete set of cardinality at most $2N$.
- (6) If p is a "good value" for which $\mathbf{K}_{\{\cdot\}}^\pm$ is a Fredholm operator on $L^p(\partial\Omega^+)$, the index of $\mathbf{K}_{\{\cdot\}}^\pm$ on $L^p(\partial\Omega^+)$ is given by

$$(6-15) \quad \text{ind}_p(\mathbf{K}_{\{\cdot\}}^\pm) = \sum_{j=1}^N I_{\{\cdot\}}^\pm(\frac{1}{p}, b, \theta_{2j}).$$

Proof. The determinant of the symbols of (6-13) and (6-14) are calculated using Theorem 2. Statements (1), (2), and (3) follow from the formulas (5-13) and (5-14). Statements (4) and (5) follow from Theorem 2, statements (8) and (9), applied to the operators (4-28). Statement (6) is the Index Theorem, Theorem 1. $\square$

Remarks. When uniqueness is shown for a double layer potential on $L^2(\partial\Omega^+)$, for the "good values" of p the index on $L^p(\partial\Omega^+)$ is the dimension of the kernel since uniqueness for the adjoint holds in $L^q(\partial\Omega^+)$, $2 \leq q < \infty$.

In contrast to the case of a finite interval, for the “good values” of p , the operators (4–28) have index $= 0$ on $[L^p(\mathbf{R}^+)]^4$. Cf. [E] or [LP, Definition 3.2] for the correct notion of principal symbol in this case; the change in argument of $\det(\text{Smb}l^{\frac{1}{2}} \mathbf{K}_{\{,\}}^{\pm})$ at $t = 0$ is killed by the change in argument at $t = \infty$.
