CORRIGENDUM TO “EMBEDDING GRAPHS INTO COLORED GRAPHS”

A. HAJNAL AND P. KOMJÁTH

There is a technical mistake in the proof of Theorem 12 of [1]. The following is a correct exposition of the idea.

Theorem 12. *It is consistent that there exists a bipartite graph on ω, ω_1 vertices, X , such that $Y \rightarrow (X)_2^2$ holds for no Y .*

Proof. Let V be a model of $\text{ZFC} + \text{CH}$. Extend it by adding a Cohen real, i.e. by $P = \{p: \text{Dom}(p) < \omega, \text{Rng}(p) \subseteq \{0, 1\}\}$. Let $G: \omega \rightarrow \{0, 1\}$ be the generic function, $p_n = G \restriction n$. Let $f_\alpha: \omega \rightarrow \omega$, $\alpha < \omega_1$ be a scale in V . For $n < \omega$, $\omega < \alpha < \omega_1$ let $\{n, \alpha\} \in E(X)$ iff $G(f_\alpha(n)) = 1$. Assume that in V^P , Y is a graph on λ , and 1 forces this fact. For $\{\alpha, \beta\} \in E(Y)$ let

$$n(\alpha, \beta) = \min\{n < \omega: p_n \Vdash \{\alpha, \beta\} \in E(Y)\}$$

and put $f(\alpha, \beta) = G(n(\alpha, \beta))$.

Notice that if for $p \in P$, $p \neq \emptyset$, p^- denotes the condition $p \restriction (\text{Dom}(p) - 1)$ and $p \Vdash \{\alpha, \beta\} \in E(Y)$, $p^- \nVdash \{\alpha, \beta\} \in E(Y)$ then $p \Vdash n(\alpha, \beta) = \text{Dom}(p)$.

We claim that $f: E(Y) \rightarrow 2$ establishes that X does not embed into Y in either color. Assume indirectly that $g: \omega \rightarrow \lambda$, $h: \omega_1 - \omega \rightarrow \lambda$ embed X into Y in the i th color. Considering that $|P| = \omega$, there are a condition $p \in G$, a set $S \in [\omega_1]^{\omega_1} \cap V$, and a sequence $\{x_\alpha: \alpha \in S\} \in V$ such that p forces all the properties of g, h listed above, and $p \Vdash h(\alpha) = x_\alpha$ for $\alpha \in S$. For $k < \omega$ let $q_k \in P$ be such that $q_k \leq p$ and $q_k \Vdash g(k) = y_k$. Put $l(k) = \text{Dom}(q_k)$. Since the f_α form a scale there is an $\alpha \in S$ such that $l(k) < f_\alpha(k)$ for some $k < \omega$. Let $r \leq q_k$ be such that $r(f_\alpha(k)) = 1$. Then $r \Vdash \{k, \alpha\} \in E(X)$ hence $r \Vdash \{y_k, x_\alpha\} \in E(Y)$. On the other hand $r^- \nVdash \{y_k, x_\alpha\} \in E(Y)$. This is true since r^- has an extension r' with $r'(f_\alpha(k)) = 0$, and then $r' \Vdash g(k) = y_k \wedge h(\alpha) = x_\alpha \wedge \{y_k, x_\alpha\} \notin E(Y)$. Then $p \geq r \Vdash n(y_k, x_\alpha) = \text{Dom}(r)$ and $r \nVdash G(\text{Dom}(r)) = i$, a contradiction.
