A CONTROLLED PLUS CONSTRUCTION FOR CRUMPLED LAMINATIONS

R. J. DAVERMAN AND F. C. TINSLEY

ABSTRACT. Given a closed n -manifold M ($n > 4$) and a finitely generated perfect subgroup P of $\pi_1(M)$, we previously developed a controlled version of Quillen's plus construction, namely a cobordism (W, M, N) with the inclusion $j: N \hookrightarrow W$ a homotopy equivalence and kernel of $i_\#: \pi_1(M) \hookrightarrow \pi_1(W)$ equalling the smallest normal subgroup of $\pi_1(M)$ containing P together with a closed map $p: W \rightarrow [0, 1]$ such that $p^{-1}(t)$ is a closed n -manifold for every $t \in [0, 1]$ and, in particular, $M = p^{-1}(0)$ and $N = p^{-1}(1)$. We accomplished this by constructing an acyclic map of manifolds $f: M \rightarrow N$ having the right fundamental groups, and W arose as the mapping cylinder of f with a collar attached along N . The main result here presents a condition under which the desired controlled plus construction can still be accomplished in many cases even when $\pi_1(M)$ contains no finitely generated perfect subgroups. By-products of these results include a new method for constructing wild embeddings of codimension one manifolds and a better understanding of perfect subgroups of finitely presented groups.

0. INTRODUCTION

Given a closed n -manifold M ($n > 4$) and perfect subgroup P of $\pi_1(M)$ whose normal closure in $\pi_1(M)$ is finitely generated as a normal subgroup, Quillen's plus construction [Q1] provides a cobordism (W, M, N) where W is a compact $(n + 1)$ -manifold with boundary $M \cup N$, the inclusion $N \subset W$ is a homotopy equivalence, and $\pi_1(N)$ is isomorphic to the quotient of $\pi_1(M)$ by the normal closure of P in $\pi_1(M)$. For some time in a continuing effort to expand on [Li] and [Da3] we have sought to obtain a somewhat more controlled version of Quillen's construction. The desired control is that of a crumpled lamination on W , namely, a closed map $p: W \rightarrow [0, 1]$ such that $p^{-1}(t)$ is a closed n -manifold for every $t \in [0, 1]$ and, in particular, $M = p^{-1}(0)$ and $N = p^{-1}(1)$. We often denote a crumpled lamination by the 4-tuple (W, M, N, p) . With finitely generated subgroups P the goal was achieved in [DT2, Theorem 5.2], basically through the construction of an acyclic map of manifolds $f: M \rightarrow N$ having the right fundamental groups, and W then arose as the mapping cylinder of f together with a collar attached along N . However, there do exist manifolds M whose fundamental groups contain

Key words and phrases. Crumpled lamination, degree one map, almost acyclic, and perfect normal subgroup.

(non-finitely-generated) perfect subgroups P for which there is no acyclic map from M to another manifold N killing P at the fundamental group level. The main result here presents a condition under which desired controlled plus construction can still be accomplished.

The word ‘crumpled’ hints at the likelihood of wildness in this sort of lamination p on (W, M, N) . Indeed, if the manifolds M and N are homotopically inequivalent, then some $p^{-1}(t)$ must be wildly embedded in W [Da3, Corollary 4.3]. Although the literature on wild and flat embeddings includes an extensive variety of results and examples, little of it readily applies to this particular setting, and a by-product of this paper is a new method for constructing wild embeddings of codimension one manifolds.

We call the unique maximal perfect subgroup of any group, G , its *wild group*, written $\text{Wild}(G)$ [C2, p. 859]. For any subset, S , of G we denote the normal closure of S in G by $\text{ncl}(S, G)$, and define it to be the smallest normal subgroup of G containing S .

The simplest example of a group G for which the methods here provide a crumpled lamination (W, M, N) , where $\pi_1(M) \cong G$ and $\pi_1(N)$ is a proper quotient of G , is the group presented as

$$(0.1) \quad G = \langle y, t | y = [y, y^{(y^t)}] \rangle$$

(here, $y^t = t^{-1}yt$). Howie [H] has shown that G has no finitely generated perfect subgroups, so our earlier construction does not apply. Furthermore, Tinsley has shown [T] that every acyclic map f from an arbitrary manifold M with fundamental group G to an ANR X has trivial π_1 -kernel. A single Tietze transformation yields the presentation

$$(0.2) \quad G = \langle y, x, t | y = [y, y^x], txt^{-1} = y \rangle.$$

Let H be the subgroup $\langle y, x | y = [y, y^x] \rangle$ and K the 2-complex arising naturally from the given presentation of H . The relevant data are:

(1) For any n -manifold M with $n > 4$ and $\pi_1(M) \cong G$ there is a locally tame embedding $f: K \hookrightarrow M$ with $f_*(\pi_1(K)) = H$.

(2) $\text{Wild}(H) = \text{ncl}(y, H) \neq 1$.

(3) $\text{ncl}(\text{Wild}(H), G) = \text{ncl}(H, G)$.

(4) $H_1(K) \cong \mathbb{Z}$ and $H_2(K) \cong 0$.

A corollary to our work is the construction of a crumpled lamination (W, M, N) with $\pi_1(M) \cong G$ and $\pi_1(N) \cong G/H \cong \mathbb{Z}$.

To state a more general theorem, we need a definition. A finite 2-complex K is said to be *almost-acyclic* if $H_2(K; \mathbb{Z}) \cong 0$ and $H_1(K; \mathbb{Z})$ is free. The main result of the paper appears in §2.

Theorem 2.0. *Suppose K is an almost acyclic 2-complex and $f: K \hookrightarrow M$ is a locally tame embedding such that*

$$f_*(\pi_1(K)) < \text{ncl}(f_*(\text{Wild}(\pi_1(K))), \pi_1(M)).$$

Then there exists a crumpled lamination (W, M, N, p) with $p^{-1}([0, \frac{3}{4})) \cong M \times [0, 1)$, $p^{-1}([\frac{3}{4}, 1]) \cong N \times [0, 1]$, and

$$\pi_1(N) \cong \pi_1(M) / \text{ncl}(\text{image}(f_*), \pi_1(M)).$$

We use Theorem 5.1 of [DT2] to characterize certain cobordisms up to h -cobordism. A cobordism (W, M, N) is a *one-sided h -cobordism* if the inclusion $j: N \hookrightarrow W$ is a homotopy equivalence. A finitely presented group is *almost-acyclic* if it has a finite presentation whose associated 2-complex is almost acyclic. Then

Theorem 2.2. *Suppose (W, M, N) is a one-sided h -cobordism with $\ker(j_\#) < H = \text{ncl}(\text{Wild}(H), \pi_1(M))$ where H is an almost acyclic subgroup of $\pi_1(M)$ and $j: M \hookrightarrow W$ is inclusion. Then (W, M, N) admits a crumpled lamination $p: W \hookrightarrow [0, 1]$ with $p^{-1}([0, \frac{3}{4})) \cong M \times [0, \frac{3}{4})$ and $p^{-1}([\frac{3}{4}, 1])$ an h -cobordism (possibly nontrivial).*

Under the hypotheses of Theorem 2.0 we show in §1 how to construct a degree one map $\Delta: M \hookrightarrow N$ with $\ker(\Delta_\#) \cong \pi_1(M)/\text{ncl}(\text{image}(f_\#), \pi_1(M))$. In this simpler setting we give many of the details necessary for the proof of Theorem 2.0. Section 2 develops relative versions of the results in the previous section necessary for the proof of the main theorem. In §3 we give the arguments sufficient to shrink the cell-like decompositions which arise at the end of §2. Other than the technology of Edwards [E2], §3 is self-contained. Finally, in the spirit of Howie [H] we further classify perfect subgroups of finitely presented groups. In particular, we introduce two new classes motivated by the geometric and group-theoretic content of this paper and investigate the behavior of these under the standard group theoretic operations.

1. ALMOST ACYCLIC COMPLEXES AND DEGREE ONE MAPS

In this section we show how to construct special degree one maps of manifolds by identifying almost acyclic complexes to points. Our construction also serves as a model for construction of a corresponding crumpled lamination in the next section.

For the remainder of this section let G be a finitely presented group and M a closed, orientable n -manifold with $n > 4$ and $\pi_1(M) \cong G$. We prove the following:

Proposition 1.0. *Suppose K is an almost acyclic 2-complex and $f: K \hookrightarrow M$ is a locally tame embedding such that*

$$f_*(\pi_1(K)) < \text{ncl}(f_*(\text{Wild}(\pi_1(K))), \pi_1(M)).$$

Then there exists a degree one map $\Delta: M \hookrightarrow N$ onto an n -manifold, N , such that Δ equals the composition $\nu \circ \delta \circ h \circ \mu$ where μ identifies $f(K)$ to a point, h is an approximate inverse to a cell-like map, δ identifies a wedge of 2-spheres to a point, and ν is an acyclic map.

A corollary to the construction of Δ is that

$$\ker(\Delta_\#) = \text{ncl}(f_*(\pi_1(K)), \pi_1(M)).$$

Denote the *commutator subgroup* of a group G by $[G, G]$. Recall that a group G is *perfect* if $G = [G, G]$. Finally, a complex is *acyclic* if its reduced homology with $\mathbb{Z}$ -coefficients is trivial.

If $\pi_1(M)$ contains a finitely generated perfect subgroup, P , then there is an acyclic 2-complex K and a nice embedding $f: K \hookrightarrow M$ with $\pi_1(M/f(K)) \cong \pi_1(M)/\text{ncl}(P, \pi_1(M))$ [DT2]. Let $\mu: M \hookrightarrow M/f(K)$ be the decomposition

map. Now, $M/f(K)$ is a generalized manifold which fails to be a manifold at a single point. $M/f(K)$ has a resolution $d: N \mapsto M/f(K)$ where N is an n -manifold and d has a single nontrivial, cell-like point-preimage [CBL] or [Qn2]. For an appropriate approximate inverse h to d , the composition $h \circ \mu: M \mapsto N$ is of degree one and $\ker((h \circ \mu)_\#) = \text{ncl}(f_\#(\pi_1(K)), \pi_1(M))$.

We use this construction as a model for building special degree one maps of manifolds where, in fact, $\pi_1(M)$ may contain no nontrivial finitely generated perfect subgroups. In particular, the kernel of the induced π_1 -homomorphism is not the normal closure of a finitely generated perfect group.

Suppose that K is an almost acyclic 2-complex, $f: K \mapsto M$ is a locally tame embedding, $f_\#: \pi_1(K) \mapsto \pi_1(M)$ is the induced homomorphism on fundamental groups, and that

$$(1.1) \quad 1 \neq f_\#(\pi_1(K)) < \text{ncl}(f_\#(\text{Wild}(\pi_1(K))), \pi_1(M)).$$

Identify a manifold mapping cylinder neighborhood N_K of $f(K)$ in M [Qn1, Theorem 3.1.1]. If M is PL, we take this neighborhood to be a regular neighborhood of $f(K)$. Let $\mu: M \mapsto M/f(K)$ be the decomposition map. Since $f(K)$ is a polyhedron, $M/f(K)$ is an ANR of finite type. Now $M/f(K)$ fails to be a manifold only at the point $x = |f(K)|$. However, it also fails to be a generalized manifold at this point. In particular,

$$(1.2) \quad H_2(M/f(K), M/f(K) - x; \mathbb{Z}) \cong H_1(K) \neq 0.$$

Details of (1.2) are included in the Appendix.

Despite the nonmanifold features, $M/f(K)$ still has a resolution in the sense that there is a nicer space, Y , and a cell-like map, $d: Y \mapsto M/f(K)$.

To construct d first observe that

$$(1.3) \quad \pi_1(M/f(K)) \cong \pi_1(M) / \text{ncl}(f_\#(\pi_1(K)), \pi_1(M)).$$

By (1.1) necessarily

$$(1.4) \quad \text{ncl}(f_\#(\pi_1(K)), \pi_1(M)) = \text{ncl}(f_\#(\text{Wild}(\pi_1(K))), \pi_1(M))$$

Since $\pi_1(K)$ is finitely generated, there is a finite collection of elements $y_i \in \text{Wild}(\pi_1(K))$ with

$$(1.5) \quad \text{ncl}(f_\#(\pi_1(K)), \pi_1(M)) = \text{ncl}(\{y_1, \dots, y_t\}, \pi_1(M)).$$

We now obtain the resolution using the technique developed by Cannon [C1] and explicated by Daverman [Da4, Chapter VII]. For each y_i there is an open grope, D_i , and a pointed (with basepoint in $\text{bdy}(D_i)$) map, $p_i: D_i \mapsto K$, such that $p_i(\text{bdy}(D_i))$ is a loop representing $y_i \in \text{Wild}(\pi_1(K))$. Since $f: K \mapsto M$ is locally tame, p_i induces a map $\bar{p}_i: D_i^+ \mapsto M/f(K)$ where D_i^+ is the closed grope, $\bar{p}_i(D_i) \subset M/f(K) - x$, and $\bar{p}_i(D_i^+ - D_i) = x$ ($D_i^+ - D_i$ is called the tip set of D_i). Since $n \geq 5$, we may assume $\bar{p}_i|D_i$ is a locally tame embedding and that the images $\bar{p}_i(D_i)$ are mutually disjoint. For each i , $1 \leq i \leq t$, we can identify a manifold mapping cylinder neighborhood, P_i , of each $\bar{p}_i(D_i) \subset M/f(K) - x$ with $r_i: P_i \mapsto \bar{p}_i(D_i)$ the associated strong deformation retraction satisfying

$$(1.6.1) \quad \lim_{* \mapsto x} (\text{diam}(r_i^{-1} \circ r_i(*))) = 0 \text{ uniformly.}$$

(1.6.2) There is a map $\tau_i: C_i^n \mapsto P_i \cup \{x\}$ where C_i^n is a crumpled cube, τ_i is an embedding over P_i , and $\tau_i^{-1}(x)$ is a wild Cantor set C_i in $\text{bdy}(C_i^n) = S^{n-1}$.

(1.6.3) There exist a CE map $\varsigma_i: B_i^n \mapsto C_i^n$, where B_i^n is an n -cell, and a collar $\lambda_i: S^{n-1} \times [0, \infty) \mapsto B_i^n$ on $\text{bdy}(B_i^n)$ such that the nontrivial point-preimages of ς_i are precisely the wild arcs $\{\lambda_i(c \times [0, 1]) | c \in C_i\}$, $\varsigma_i|_{\lambda_i(S^{n-1} \times 0)} = \text{identity}$, and $\lambda_i(C_i \times 1)$ is tamely embedded in $\text{int}(B_i^n)$.

Identify loops $\{l_1, l_2, \dots, l_s\}$ in K representing the generators of $H_1(K; \mathbb{Z})$. Homotopically move each $f(l_j)$ off $f(K)$ in M to an embedded loop, $\hat{l}_j$, so that the homotopy is an isotopy off $f(K)$ and misses $\mu^{-1}(\bigcup_{i=1}^t P_i)$. By (1.5) and general position, $\hat{l}_j$ bounds a disk with holes, Θ_j , so that

$$(1.7.1) \quad (\Theta_j - \text{bdy}(\Theta_j)) \subset \left(M - f(K) - \mu^{-1} \left(\bigcup_{i=1}^t P_i \right) \right),$$

$$(1.7.2) \quad \text{bdy}(\Theta_j) - \hat{l}_j \subset \mu^{-1} \left(\bigcup_{i=1}^t P_i \right)$$

with the inclusion an embedding on each component.

Let

$$(1.8) \quad Y = \left(M/f(K) - \left(\bigcup_{i=1}^t \text{int}(P_i) \right) \right) \cup \left(\bigcup_{i=1}^t B_i^n \right)$$

where B_i^n is attached to $\text{bdy}(P_i) \cup \{x\}$ by the map $\tau_i \circ \varsigma_i|_{S^{n-1}}$.

Lemma 1.1. *Y is an ANR.*

Proof. What distinguishes this setting from that of Cannon is that $M/f(K)$ is not a generalized manifold. However, well-known results would apply if each $\tau_i: C_i^n \mapsto P_i \cup \{x\}$ were an embedding. We show how to reduce our situation to the case of an embedding for $n \geq 6$. We omit details for the case $n = 5$ which requires altering K in the manner discussed at the beginning of the next section.

Without much loss of generality, there is a tame embedding $\gamma: K \times [0, 1] \mapsto \text{int}(N_K)$ with $\gamma|_{K \times \{1\}} = f$. To see why, use general position to find an embedding $f_1: K \mapsto \text{bdy}(N_K)$ homotopic to f in N_K , let γ denote the product embedding $f_1 \times \text{id}: K \times [0, 1] \mapsto \text{bdy}(N_K) \times [0, 1]$ into a collar on $\text{bdy}(N_K)$, and replace the original f with $\gamma|_{K \times \{1\}}$. Let Γ be the usc decomposition of M consisting of points together with the nondegenerate elements $\{\gamma(K \times \{t\}) | t \in [0, 1]\}$. Now we can embed each closed grope, D_i^+ , in M/Γ , by spreading out successive grope stages to different levels of the collar on $\text{bdy}(N_K)$. This embeds each tip set in the image of the nondegeneracy set, an arc, α . Here M/Γ is an ANR (it is a union of more obvious ANRs $(M - \text{int}(N_K))/\gamma(K \times 0)$, $(\text{bdy}(N_K)/\gamma(K \times 0)) \times [0, 1]$, and a third piece homeomorphic to $N_K/\gamma(K \times 0)$). As in [CBL] or [Da4, p. 276], when we take thickenings, P'_i , of the embedded gropes, then

$$Y' = M/\Gamma - \left(\bigcup \text{int}(P'_i) \right) \cup \left(\bigcup B_i^n \right)$$

is an ANR. Finally, $Y \cong Y'/\alpha$ so Y is an ANR [Sm]. This completes the proof of Lemma 1.1.

The construction identifies a cell-like map $d: Y \mapsto M/f(K)$ which has a single nontrivial point-preimage, $d^{-1}(x)$, homeomorphic to a wedge of arcs, $\bigvee_{i \in \mathbb{C}} A_i$, where $\mathbb{C}$ is a Cantor set and A_i is an arc. Let y be the wedge point. Then the map $d: (Y, y) \mapsto (M/f(K), x)$ induces isomorphisms on local homology. In particular, $Y - y$ is a manifold and

$$(1.9) \quad \begin{aligned} H_2(Y, Y - y; \mathbb{Z}) &\cong H_2(Y, Y - d^{-1}(x)) \cong H_2(M/f(K), M/f(K) - x; \mathbb{Z}) \\ &\cong H_1(K; \mathbb{Z}) \end{aligned}$$

and each is finitely generated. We discuss this fact also in the Appendix.

Now, let κ_j be the image under $d^{-1} \circ \mu$ of the homotopy taking $f(l_j)$ to $\hat{l}_j$. Then

$$(1.10) \quad \Theta'_j = (d^{-1} \circ \mu(\Theta_j) \cup (\kappa_j - f(l_j)) \cup \{y\}) \subset ((Y - d^{-1}(x)) \cup \{y\})$$

is a disk with holes with one fewer boundary components than Θ_j ($f(l_j)$ is mapped to y). The previous discussion allows that each boundary component of Θ'_j is homotopically trivial in the manifold $(Y - \{y\})$. General position in $(Y - \{y\})$ yields a wedge of 2-spheres, $S = \bigvee_{j=1}^s S_j^2$, locally tame modulo the wedge point y where each S_j^2 arises naturally as Θ'_j with disks attached to boundary components. By construction, the inclusion of S into Y induces isomorphisms on homology. In particular,

$$(1.11) \quad H_2(S; \mathbb{Z}) \xrightarrow{\cong} H_2(S, S - y; \mathbb{Z}) \xrightarrow{\cong} H_2(Y, Y - y; \mathbb{Z}) \cong \mathbb{Z}^s$$

where $\mathbb{Z}^s$ denotes the direct sum of s copies of $\mathbb{Z}$. Let $Z = Y/S$, $\delta: Y \mapsto Z$ be the decomposition map, and $z = \delta(S)$.

Lemma 1.2. Z is a generalized n -manifold.

Proof. A detailed proof appears in the Appendix. However, the idea is as follows. First, since Y and S are both ANRs, so is Z . Next, since the 2-complex K is almost acyclic, then the complex, $\bar{K}$, obtained by abstractly attaching disks to loops representing the generators of $H_1(K; \mathbb{Z})$, is acyclic. So if $\bar{K}$ were embedded in an n -manifold, M , then $M/\bar{K}$ would be a generalized manifold. Our construction is homologically equivalent to this. We first collapse K obtaining M/K . Next we apply the inverse of a cell-like map which does not affect local homology. Finally, we identify the disks attached to representatives of the generators of $H_1(K; \mathbb{Z})$ (which at this stage are topologically a wedge of 2-spheres), collapse them out, and, in effect, complete the collapse of $\bar{K}$ in two steps.

Since Z is a manifold except possibly at z , then Z is a manifold if given any neighborhood U of z in Z there exists a neighborhood V of z in Z so that any map $g: \text{bdy}(B) \mapsto V - z$ extends to a map $\bar{g}: B \mapsto U - z$ where B is a 2-disk. As in [C1, p. 107], this local property implies Z has the DDP, and then Z is a manifold by [Qn3].

Lemma 1.3. If $[\pi_1(K), \pi_1(K)] = \text{Wild}(K)$, then Z is a manifold.

Proof. Let $z \in U^{\text{nbhd}} \subset Z$. Since Z is an ANR, there exist a neighborhood V of z in U and a strong deformation retraction of V to z in U . Let

$g: \text{bdy}(B) \mapsto V$ be a mapping of the boundary of a disk. Since S is simply connected, there is a map $g_1: B \mapsto \delta^{-1}(U) \subset Y$ so that $\delta \circ g_1|_{\text{bdy}(B)} = g|_{\text{bdy}(B)}$. But $(S - y)$ is locally tame in $(Y - y)$ so we may adjust g_1 slightly to make $g_1(B) \cap (S - y) = \emptyset$. Finally, since $d^{-1}(x) - y$ has embedding codimension 2 in $Y - y$ and Y rather obviously satisfies the disjoint arc-disk property of [Da2], we can adjust slightly g_1 so $(d \circ g_1)^{-1}(x)$ is 0-dimensional and $\delta \circ g_1|_{\text{bdy}(B)}$ is homotopic in $V - z$ to $g|_{\text{bdy}(B)}$.

Since $d: Y \mapsto M/f(K)$ is a homeomorphism over $M/f(K) - \text{int}(\bigcup P_i)$, we may choose the manifold mapping cylinder neighborhood, N_K , of K in M so that $d^{-1}(\mu(N_K) - \bigcup P_i - x) \subset \delta^{-1}(V)$. By (1.6.1) there is a smaller manifold mapping cylinder neighborhood, N'_K , so that for any $(n-3)$ -complex in $\mu(N'_K) - x$ there is a general position isotopy with support in $\mu(N_K) - x$ which moves that complex into $(M/f(K) - x - \bigcup P_i)$.

For any neighborhood, U_1 (we emphasize that U_1 is chosen independent of U and V and may be arbitrarily small) with $y \in U_1$, surface topology and the 0-dimensionality of $g_1^{-1}(y)$ allow us to identify a disk with holes, $B' \subset B - g_1^{-1}(y)$, so that $\text{bdy}(B) \subset \text{bdy}(B')$, and for each component, $\rho B'_k$, of $\text{bdy}(B')$ not equal to $\text{bdy}(B)$, $g_1(\rho B'_k) \subset U_1 - y$.

We focus on a particular loop $\gamma_k = g_1|_{\rho B'_k}$. Since $d^{-1}(x) - y$ has embedding codimension 2 in $Y - y$, we may assume $\text{image}(\gamma_k) \cap d^{-1}(x) = \emptyset$. Thus, the loop γ_k is homotopic in $\delta^{-1}(U - z)$ to a loop γ'_k with image in $d^{-1}(\mu(N'_K) - x - \bigcup P_i)$. To see this, note first that $\tau_i \circ \varsigma_i: B_i^n \mapsto C_i^n \mapsto P_i \cup \{x\}$ is an embedding over $\text{image}(\gamma_k) \cap P_i$. Then, using the fact that the Cantor set, C_i , has embedding codimension 2 in $\text{bdy}(B_i^n)$, build a homotopy in $\bigcup B_i^n$ which fixes $\text{bdy}(B_i^n)$ and pushes $(\varsigma_i^{-1} \circ \tau_i^{-1}(\text{image}(\gamma_k))) \cap \text{int}(B_i^n)$ along a short collar to $\text{bdy}(B_i^n) - C_i$. For U_1 sufficiently small, the image under $\tau_i \circ \varsigma_i$ of the tracks of the homotopy will stay inside $\delta^{-1}(U - z)$ with the final stage in $d^{-1}(\mu(N'_K) - x - \text{int}(\bigcup P_i))$. But $d^{-1}(\bigcup \text{bdy}(P_i))$ is locally tame and, thus, collared in $Y - (\bigcup \tau_i \circ \varsigma_i(B_i^n))$ so γ'_k results from pushing the final stage off $(\bigcup \tau_i \circ \varsigma_i(B_i^n))$ using so little of the collar that $\text{image}(\gamma'_k)$ remains in $d^{-1} \circ \mu(N'_K)$.

Since $\text{Wild}(\pi_1(K)) = [\pi_1(K), \pi_1(K)]$, we see that

$$(1.12) \quad \{\text{Wild}(\pi_1(K)), |l_1|, \dots, |l_s|\}$$

generates $\pi_1(K)$. Since $\pi_1(K)$ is finitely generated, we may assume that the elements

$$(1.13) \quad \{y_1, \dots, y_t, |l_1|, \dots, |l_s|\}$$

generate $\pi_1(K)$ (we may have to enlarge t).

By regular neighborhood theory,

$$(1.14) \quad \mu(N'_K) - x \cong \text{bdy}(N'_K) \times (0, 1]$$

and each has fundamental group isomorphic to $\pi_1(K)$. The previous paragraph shows $d \circ \gamma'_k$ bounds a disk with holes in $\mu(N'_K) - x$ so that each other boundary component represents a composite of elements from $\{y_1, \dots, y_t, |l_1|, \dots, |l_s|\}$.

Let β be a loop in $\mu(N'_K) - x$ representing a y_i and recall the earlier grope construction. For any positive integer m , $y_i = \prod_{j=1}^m y_{ijm}$ where y_{ijm} belongs

to $(\pi_1(K))^{(m)}$, the m th term in the derived series of $\pi_1(K)$, and is represented by a boundary curve in the m th stage of the grope, D_i . We realize this equality as a disk with holes in $\mu(N'_K) - x$ having β as one boundary component and each other representing a y_{ijm} . After performing this construction for each β making up the composite referred to in the previous paragraph and repeating for all boundary components of the disk with holes other than $d \circ \gamma'_k$, we obtain a larger disk with holes having $\text{image}(d \circ \gamma'_k)$ as one boundary component and each other boundary component representing either an $|l_j|$ or a y_{ijm} . By general position, (1.6.1), and (1.14) we may also assume that each other boundary component lies in $(d(U_1) - \bigcup P_i)$.

We use general position fixing the boundary of the disk with holes and our choice of N'_K to move the disk with holes into $(\mu(N_K) - \bigcup P_i - x)$. Then d^{-1} maps this back to a disk with holes in $d^{-1}(\mu(N_K) - \bigcup P_i - x)$ with $\text{image}(\gamma'_k)$ a boundary component. A boundary component representing an $|l_j|$ may be capped off in with a disk close to $(S_j^2 - y)$. For m sufficiently large a boundary component representing a y_{ijm} may be capped off in $d^{-1}((\mu(N_K) - \bigcup P_i) - S) \subset \delta^{-1}(U) - S$. This cap necessarily will hit $d^{-1}(x) - y$.

Putting together all of the disks with holes and corresponding caps yields a map $g_2: B \mapsto (\delta^{-1}(U) - S)$ with $\delta \circ g_2|_{\text{bdy}(B)} = g|_{\text{bdy}(B)}$. We take as our map, $\bar{g} = \delta \circ g_2$.

This completes the proof of Lemma 1.3.

Lemma 1.4. *If $\text{Wild}(\pi_1(K)) = \text{ncl}(\{y_1, \dots, y_m\}, \pi_1(K))$, then there is an almost acyclic 2-complex, K' , and a locally tame embedding $f': K' \hookrightarrow M$ satisfying the hypotheses of Lemma 1.3, with*

$$\text{ncl}(f'_\#(\pi_1(K')), \pi_1(M)) \cong \text{ncl}(f_\#(\pi_1(K)), \pi_1(M)).$$

Proof. For each $y_i \in \text{Wild}(\pi_1(K))$, necessarily $y_i = \prod_{j=1}^{n_i} [u_{ij}, v_{ij}]$ where $u_{ij}, v_{ij} \in \text{Wild}(\pi_1(K))$. We begin the construction of K' with a bouquet of m simple closed curves, one for each y_i . To the i th simple closed curve we attach a disk with n_i handles representing the relation, $y_i = \prod_{j=1}^{n_i} [u_{ij}, v_{ij}]$. Finally, since each u_{ij} (respectively v_{ij}) is in $\text{ncl}(\{y_1, \dots, y_m\}, \pi_1(K))$, we attach a disk with holes with one boundary component attached to the meridian (respectively longitude) of handle (i, j) and each other boundary component attached to one of the original simple closed curves. Since all of the relations above are relations in $\pi_1(K)$, the resulting complex, K' , embeds in a regular neighborhood of $f(K)$ in M with the image of the i th simple closed curve of $K'^{(1)}$ representing $y_i \in \pi_1(K)$. It is a straightforward exercise to show that K' is almost acyclic with $H_1(K'; \mathbb{Z})$ having a generator for each boundary of each disk with holes which attaches to a $|y_i|$ and that $\text{Wild}(\pi_1(K')) = [\pi_1(K'), \pi_1(K')]$.

Lemma 1.5. *If neither the hypotheses of Lemma 1.3 nor Lemma 1.4 hold, then there is an acyclic map $\nu: Z \hookrightarrow N$ where N is an n -manifold and $\delta \circ d^{-1} \circ \mu$ is an embedding over $S(\nu)$. the singular set of ν .*

Currently, no known examples fail to satisfy the hypotheses of Lemma 1.4. The question concerning the necessity of Lemma 1.5 is related to a problem raised by Wall [W, Problem F10, p. 387].

Proof. A slight modification to the proof of Lemma 1.1 yields a map $F: K \times [0, 1] \mapsto M$ so that $F|_{K \times \{1\}} = f$ and $F|(K^{(1)} \times [0, 1] \cup (\bigcup K \times t_k))$ is an

embedding into $(M - \mu^{-1}(\bigcup P_i) - \mu^{-1} \circ d(S))$ for a sequence $\{t_k\}$ increasing to 1. For each representative l_j of a generator of $H_1(K; \mathbb{Z})$ and each t_k , $d^{-1} \circ \mu \circ F(l_j \times t_k)$ is a loop in $Y - S$ which bounds a disk in $Y - S$ close to S_j^2 . Let L_k be a 2-complex in $Y - S$ obtained by attaching disks to each such generator so that $\{\delta(L_k)\}$ is a mutually disjoint, null sequence of acyclic 2-complexes in $Z - z$. Let $\{N_{L_k}\}_{k=1}^\infty$ be a mutually disjoint sequence of manifold mapping cylinder neighborhoods of the $\{L_k\}$'s in $Z - z$.

Each N_{L_k} is a homology cell. Daverman and Tinsley [DT2, Corollary 4.5] show how to construct an acyclic map, $\nu_k: N_{L_k} \mapsto \mathcal{E}_k$, where ν_k is the identity on the boundary, ν_k is an embedding over the complement of a Cantor set, and $\mathcal{E}_k$ is a contractible manifold. Let $\nu: Z \mapsto N$ be the map which is the identity on $Z - (\bigcup N_{L_k})$ and equal to ν_k on N_{L_k} and N has the identification topology induced by ν .

Thus, N is a manifold except at possibly $\nu(z)$. Let W be any neighborhood of $\nu(z)$ in N . Let $U = \nu^{-1}(W)$. We now argue as in Lemma 1.3 except we choose V to be ν -saturated and work entirely over $Z - (\bigcup N_{L_i})$. The latter is possible by general position since each N_{L_k} has a 2-spine. We proceed as before until obtaining the loop γ'_k . The loop, $d \circ \gamma'_k$, is homotopic in $(\mu(N_K) - x - \bigcup P_i)$ to a loop γ''_k in an appropriate N_{L_i} close to $f(K)$. The loop $\nu \circ \gamma''_k$ bounds a disk in $\mathcal{E}_i$. We map everything into $N - \nu(z)$ and see that N is an n -manifold and the proof of Lemma 1.5 is complete.

Proof of Proposition 1.0. For an appropriate approximate inverse, $h: M/f(K) \mapsto Y$, to d , $\Delta = \delta \circ h \circ \mu: M \mapsto N$ (Lemma 1.3 or Lemma 1.4) or $\Delta = \nu \circ \delta \circ h \circ \mu: M \mapsto N$ (Lemma 1.5) is the desired degree one map.

2. CRUMPLED LAMINATIONS

We prove the main theorem of this paper.

Theorem 2.0. *Suppose K is an almost acyclic 2-complex and $f: K \mapsto M$ is a locally tame embedding such that*

$$f_*(\pi_1(K)) < \text{ncl}(f_*(\text{Wild}(\pi_1(K))), \pi_1(M)).$$

Then there exists a crumpled lamination (W, M, N, p) with $p^{-1}([0, \frac{3}{4})) \cong M \times [0, 1)$, $p^{-1}([\frac{3}{4}, 1]) \cong N \times [0, 1]$, and

$$\pi_1(N) \cong \pi_1(M) / \text{ncl}(\text{image}(f_*), \pi_1(M)).$$

The construction begins with $M \times [-1, 1]$. Assume $f: K \mapsto M$ is a locally tame embedding of K in M which satisfies (1.1)–(1.5). We adjust f slightly as follows. Let Q be the flat boundary of a topological regular neighborhood N_K of $f(K)$ in M . Then f is homotopic in this neighborhood to $f_1: K \mapsto Q$ where f_1 is either an embedding ($n > 5$) or an immersion ($n = 5$) with, at worst, double points. In the latter case $f_1(K)$ is still an almost acyclic compactum since it has the same homotopy type as K wedged with a bouquet of circles (one circle for each pair of double points). Also, f_1 also satisfies

$$(2.1) \quad \text{ncl}(f_{1*}(\pi_1(K)), \pi_1(M)) \cong \text{ncl}(f_*(\pi_1(K)), \pi_1(M)).$$

So we take f_1 for f and, since Q is flat in M , we assume

$$(2.2) \quad f(K) \subset Q \cong Q \times \{0\} \subset Q \times (-\infty, \infty) \subset M \cong M \times \{0\} \subset M \times [-1, 1].$$

By the *spin* of a space $B \times [0, \infty)$ we mean the quotient space obtained from $B \times [0, \infty) \times S^1$ by identifying all circles of the form $b \times 0 \times S^1$, $b \in B$. The spin structure provides generalized polar coordinates $\langle b, r, \theta \rangle$ for $B \times \mathbb{R}^2$ where $r \in [0, \infty)$ and $\theta \in S^1$. For ease of notation we assume the S^1 coordinate is a complex number (shown in bold) of modulus 1 and that the polar subspace, $b \times [0, \infty) \times \{-1, 1\}$ ($b \times 0 \times -1 \equiv b \times 0 \times 1$, $1 \in S^1$, of course), naturally corresponds to $B \times \mathbb{R}^1 \times 0 \subset B \times \mathbb{R}^2$.

In our setting we give the neighborhood

$$(2.3) \quad (Q \times (-\infty, \infty)) \times (-\epsilon, \epsilon) \subset M \times [-1, 1]$$

coordinates $\langle q, r, \theta \rangle$ by spinning $Q \times [0, \infty)$ in $M \times (-1, 1) \cong M \times (-\infty, \infty)$ and assume

$$(2.4) \quad Q \times [0, \infty) \times \{-1, 1\} \subset M \times 0 \subset M \times [-1, 1].$$

We will refer to

$$(2.5) \quad Q \times 0 \times S^1 / \{q \times 0 \times S^1 | q \in Q\} \subset Q \times [0, \infty) \times S^1 / \{q \times 0 \times S^1 | q \in Q\}$$

simply as Q .

We will now modify the construction of §1. By (2.1) the same finite collection of elements $y_i \in \text{Wild}(\pi_1(K))$ satisfies

$$(2.6) \quad \text{ncl}(f_{\#}(\pi_1(K)), \pi_1(M)) = \text{ncl}(\{y_1, \dots, y_i\}, \pi_1(M)).$$

We mod out $f(K)$ and let

$$(2.7) \quad x = |f(K)| \in Q/f(K) \subset M \times 0/f(K) \subset M \times [-1, 1]/f(K)$$

with $\mu: M \times [-1, 1] \mapsto M \times [-1, 1]/f(K)$ the decomposition map. As in §1 we obtain a map $\bar{p}_i: D_i^+ \mapsto Q \times [0, \infty)/f(K)$ where D_i^+ is a closed grope, $\bar{p}_i(D_i^+ - D_i) = x$, $\bar{p}_i|_{D_i}$ is a locally tame embedding, $\bar{p}_i(\text{bdy}(D_i))$ is a loop representing $y_i \in G$, and so the D_i 's have mutually disjoint pinched regular neighborhoods $P_i \subset Q \times (0, \infty)$. As before we remove the interior of each P_i and attach a cell, B_i^n , via a map

$$(2.8) \quad (\tau_i \circ \varsigma_i | \text{bdy}(B_i^n)): \text{bdy}(B_i^n) \mapsto \text{bdy}(P_i) \cup x$$

satisfying (1.6.1)–(1.6.3). Now, simultaneously we make this replacement for each $\theta \in S^1$ and denote by Q_{θ}^+ the space

$$(2.9) \quad \left(\left(Q \times (0, \infty) - \left(\bigcup_{i=1}^t \text{int}(P_i) \right) \right) \cup \left(\bigcup_{i=1}^t B_i^n \right) \right) \times \theta.$$

We obtain a space, $\mathscr{Y}$, and a cell-like map $d: \mathscr{Y} \mapsto M \times [-1, 1]/f(K)$ where d has a single nontrivial point-preimage, $d^{-1}(x)$, homeomorphic to a wedge of 2-disks, $\bigvee_{\alpha \in C} B_{\alpha}^2$ (C a Cantor set), with wedgepoint y . The Cantor set, C , arises naturally as $C = \bigcup_{i=1}^t C_i$ where $C_i = \tau_i^{-1}(x) \subset C_i^n$. There is a natural subspace $Y \subset \mathscr{Y}$ so that $(d|_Y): Y \mapsto M \times 0/f(K)$ is a cell-like map with single nontrivial point-preimage $(d|_Y)^{-1}(x)$ homeomorphic to a wedge of arcs, $\bigvee_{\alpha \in C} A_{\alpha}$, where $A_{\alpha} = B_{\alpha}^2 \cap Y$. There is a natural projection map $e_{\alpha}: B_{\alpha}^2 \mapsto A_{\alpha}$ (not unlike the map $B^2 \xrightarrow{(r,s) \mapsto r} B^1$). In particular, we may assume

$$(2.10) \quad e_{\alpha}^{-1}(y) - y \subset Q_i^+ \quad \text{where } i \in S^1$$

and Q_i^+ lies in the same component of $\mathcal{Y} - Y$ as does $d^{-1} \circ \mu(M \times \{-1\})$.

The space Y of this section is quite similar to the Y of §1. It is an ANR which is a manifold except at y and has the same local homology at y . The only difference is that there are two gropes used in this section (corresponding to $-1, 1 \in S^1$) for each grope in §1. The extra gropes affect neither the local homology nor the ANR status of Y .

As before, we construct a wedge of 2-spheres, $S = \bigvee_{j=1}^s S_j^2$ with wedgepoint y , in Y so that the inclusion of $S - y$ into $Y - y$ is locally tame and,

$$(2.11) \quad H_2(S; \mathbb{Z}) \xrightarrow{\cong} H_2(S, S - y; \mathbb{Z}) \xrightarrow{\cong} H_2(Y, Y - y; \mathbb{Z}) \cong \mathbb{Z}^s.$$

But in addition,

$$(2.12) \quad H_2(S; \mathbb{Z}) \xrightarrow{\cong} H_2(S, S - y; \mathbb{Z}) \xrightarrow{\cong} H_2(\mathcal{Y}, \mathcal{Y} - y; \mathbb{Z}) \cong \mathbb{Z}^s.$$

We identify an usc cell-like decomposition of $\mathcal{Y}$. Denote by $\mathcal{Y}^+$ the closure of the component of $\mathcal{Y} - Y$ containing Q_i^+ . Let $(D_\alpha, A_\alpha) \subset (\mathcal{Y}, Y)$ be one of the (disk, arc) pairs constructed above. Denote by $\mathcal{G}^+$ the usc decomposition of $\mathcal{Y}$ consisting of points, special element $g_0 = \{(\bigcup e_\alpha^{-1}(y)) \cap \mathcal{Y}^+\}$, and arcs $\{e_\alpha^{-1}(a) | a \in (A_\alpha - y), \alpha \in \mathbb{C}\}$.

Lemma 2.1. *The decomposition $\mathcal{G}^+$ is shrinkable.*

Proof of Lemma 2.1. We first shrink g_0 and then show how to apply Corollary 3.4 of the next section. But $g_0 - y \cong \mathbb{C} \times (0, 1]$ is contained in the locally tame codimension one submanifold Q_i^+ of $\mathcal{Y} - y$ so $g_0 - y$ is standardly embedded in $\mathcal{Y}^+$. By fairly standard ‘radial’ shrinking methods first introduced by Bing [B or Da4, §8], g_0 can be shrunk to the point y by a pseudo-isotopy supported in an arbitrary neighborhood of $g_0 - y$. If $\pi_{g_0}: \mathcal{Y} \mapsto \mathcal{Y}/g_0$ is the identification map, then we have a homeomorphism $h_1: \mathcal{Y} \mapsto \mathcal{Y}/g_0$ with $h_1|_Y = \pi_{g_0}|_Y$.

We now apply Corollary 3.4 of the next section. For each i , $1 \leq i \leq t$, let U_i be an open neighborhood of $\pi_{g_0}(\text{int}(B_i^n))$ in $\mathcal{Y}/g_0$ so that

$$(2.13.1) \quad U_i \cap U_j = \emptyset \quad \text{for } i \neq j,$$

$$(2.13.2) \quad \text{clos}(U_i) = \pi_{g_0}(\text{bdy}(P_i) \cup x).$$

For appropriate saturated neighborhoods, $\mathcal{U}_i$, and after possible slight adjustments of the 2-manifold, $T = \pi_{g_0}(S - y)$, we piece together a homeomorphism $h_2: \mathcal{Y}/g_0 \mapsto \mathcal{Y}/\mathcal{G}^+$ so that the composition $h = h_2 \circ h_1: \mathcal{Y} \mapsto \mathcal{Y}/\mathcal{G}^+$ satisfies $h|_S = \pi_{\mathcal{G}^+}|_S$. We let the triple

$$(\mathcal{Z}, Z, z) = (\pi_{\mathcal{G}^+}(\mathcal{Y})/h(S), \pi_{\mathcal{G}^+}(Y)/h(S), h(y))$$

and $(\bar{\delta}, \delta): (\mathcal{Y}, Y) \mapsto (\mathcal{Z}, Z)$ denote the decomposition map. We observe that the pair $(\mathcal{Z}, Z)$ is a generalized manifold pair which is a manifold pair except possibly at z and that $\mathcal{Z}^+ = (\bar{\delta}(\mathcal{Y}^+) - Z)$ is homeomorphic to $M \times [0, \frac{3}{4})$.

We repeat the analysis of §1. If the hypotheses of either Lemma 1.3 or 1.4 applies, then Z is a manifold, and we let $(W, N) = (\mathcal{Z}, Z)$. If Lemma 1.5 applies, the resulting acyclic map $\nu: Z \mapsto N$ trivially extends to an acyclic map $\xi: \mathcal{Z} \mapsto W$ with the same singular set. In any event, the resulting pair, (W, N) , is a manifold pair since the point, $\xi(z)$, is 1-LCC embedded in W .

If Lemma 1.5 and ν were indeed necessary, N may not be 1-LCC embedded in $(W - \mathcal{Z}^+)$. In this case, we may reembed $\mathcal{Z}^+ \cup N$ in W so that N has a collar in $(W - \mathcal{Z}^+)$ homeomorphic to $N \times [\frac{3}{4}, 1]$ [Da1]. Then there is an obvious crumpled lamination map $p : \mathcal{Z}^+ \cup N \times [\frac{3}{4}, 1] \mapsto [0, 1]$ satisfying the conclusion of Theorem 2.0.

3. DECOMPOSITION THEORY

We summarize the decomposition theory necessary to complete the crumpled lamination constructed in §2.

Let $\lambda : S^{n-1} \times [0, 1] \rightarrow S^{n-1} \times [0, \infty)$ be a collar on the boundary; that is, λ is an embedding with $\lambda(s, 0) = (s, 0)$ for all $s \in S^{n-1}$. In this setting we definitely do not assume that $\lambda(S^{n-1} \times 1)$ is bicollared in the image. Suppose C is a fixed compact subset of S^{n-1} . The spin (recall §2) $S^{n-1} \times R^2$ of $S^{n-1} \times [0, \infty)$ contains a distinguished space

$$(3.1) \quad Sp(\lambda, C) = (\lambda(C \times I) \times S^1 / \sim) \cong (C \times I \times S^1 / \sim) \cong C \times B^2,$$

given by the obvious identification. We denote $Sp(\lambda, S^{n-1})$ more simply as $Sp(\lambda)$ and note that in these representations $Sp(\lambda, C) \subset Sp(\lambda)$ corresponds to $C \times B^2 \subset S^{n-1} \times B^2$. The projection $e : B^2 \rightarrow B^1$ sending $(x, y) \in B^2$ to $x \in B^1$ induces what we call the *vertical arc decomposition* $\mathcal{G}(\lambda, C)$ of $S^{n-1} \times R^2$ associated with λ and C ; it consists of the point preimages under the associated map $\text{Id} \times e : C \times B^2 \rightarrow C \times B^1$ together with the singletons from outside $Sp(\lambda, C)$.

Theorem 3.1. *Suppose $\lambda : S^{n-1} \times [0, 1] \rightarrow S^{n-1} \times [0, \infty)$ is a collar on the boundary, C is a compact k -dimensional subset of S^{n-1} such that $\lambda(C \times 1)$ is 1-LCC embedded in $S^{n-1} \times [0, \infty)$, $n \geq 4$, and $k \leq n - 3$. Then the decomposition map $S^{n-1} \times R^2 \rightarrow S^{n-1} \times R^2 / \mathcal{G}(\lambda, C)$ is a near-homeomorphism.*

Proof. In this setting Edwards's Cell-like Approximation Theorem [E2] establishes that it suffices to show $S^{n-1} \times R^2 / \mathcal{G}(\lambda, C)$ has the DDP. Since any two mappings μ_1, μ_2 of B^2 to the quotient space can be approximated by images of lifts $\psi_1, \psi_2 : B^2 \rightarrow S^{n-1} \times R^2$, it is enough to show how to approximate ψ_1, ψ_2 by mappings ψ'_1, ψ'_2 , respectively, such that no element of $\mathcal{G}(\lambda, C)$ meets both $\psi_1(B^2)$ and $\psi_2(B^2)$. The 1-LCC condition on $\lambda(C \times 1) \subset S^{n-1} \times [0, \infty)$ implies that the inclusion

$$(3.2) \quad \lambda(C \times 1) \times S^1 \subset (S^{n-1} \times R^2) \setminus (S^{n-1} \times \{\text{origin}\}) \cong S^{n-1} \times (0, \infty) \times S^1$$

is a 1-LCC embedding. Hence, ψ_1, ψ_2 each can be approximated so as to avoid $\lambda(C \times 1) \times S^1 \subset C \times \text{bdy}(B^2) \subset \partial(Sp(\lambda))$. We shall further modify these adjusted images in $Sp(\lambda)$, and for this next operation we refer to the projection map

$$(3.3) \quad e' = \text{Id} \times e : S^{n-1} \times B^2 \rightarrow S^{n-1} \times B^1.$$

We approximate ψ_i by maps ψ'_i ($i = 1, 2$) such that ψ_i, ψ'_i agree outside $\psi_i^{-1}(S^{n-1} \times \text{Int } B^2)$ and

$$(3.4) \quad e' \psi'_1(\psi_1^{-1}(S^{n-1} \times \text{Int } B^2)) \cap e' \psi'_2(\psi_2^{-1}(S^{n-1} \times \text{Int } B^2)) \cap C \times B^1 = \emptyset.$$

For $n \geq 5$ this is simple general position; for $n = 4$ it still can be accomplished by first making the relevant images $e' \psi'_1$ and $e' \psi'_2$ intersect in a locally finite

set in $S^{n-1} \times \text{Int } B^1$ and then, with a controlled ambient homeomorphism of $S^{n-1} \times \text{Int } B^1$, slipping this intersection off $C \times B^1$, which is nowhere dense in $S^{n-1} \times \text{Int } B^1$.

Corollary 3.2. *Under the hypotheses of Theorem 3.1, suppose $\mathcal{G}$ is another upper semicontinuous decomposition of $S^{n-1} \times R^2$ into points and arcs, where every arc from $\mathcal{G}$ is a subarc of one in $\mathcal{G}(\lambda, C)$. Then the decomposition map $S^{n-1} \times R^2 \rightarrow S^{n-1} \times R^2/\mathcal{G}$ is also a near-homeomorphism.*

This follows directly from the proof of Theorem 3.1.

In particular, we will exploit a related upper half decomposition $\mathcal{G}^+$, non-degenerate elements of which are the intersections of those from $\mathcal{G}(\lambda, C)$ with $C \times B_+^2 \subset C \times B^2$, where, of course, $B_+^2 = \{(x, y) \in B^2 \mid y \geq 0\}$. Let $\pi^+: S^{n-1} \times R^2 \rightarrow S^{n-1} \times R^2/\mathcal{G}^+$ denote the associated decomposition map. We will need the following relative version of Corollary 3.2.

Theorem 3.3. *Suppose $\lambda: S^{n-1} \times [0, 1] \rightarrow S^{n-1} \times [0, \infty)$ is a collar on the boundary, $n \geq 4$, and C is a compact 0-dimensional subset of S^{n-1} such that $\lambda(C \times 1)$ is 1-LCC embedded in $S^{n-1} \times [0, \infty)$. Suppose that, in addition, $\eta: T \rightarrow \text{Int}(Sp(\lambda) \cap (S^{n-1} \times B^1))$ is a locally flat, closed embedding of a 2-manifold T . Then η can be approximated, arbitrarily closely, by another embedding $\eta': T \rightarrow S^{n-1} \times \text{Int } B^1$ such that for every $\mathcal{G}^+$ -saturated open cover $\mathcal{U}$ of $S^{n-1} \times R^2$ there exists a homeomorphism $h: S^{n-1} \times R^2 \rightarrow S^{n-1} \times R^2/\mathcal{G}^+$ satisfying $h|_{\eta'(T)} = \pi^+|_{\eta'(T)}$ and h is $\pi^+(\mathcal{U})$ -close to π^+ .*

Proof. The key is to approximate η , in a fashion comparable to that of Theorem 3.1, to make the projection q of $\eta'(T) \cap \text{Int}(Sp(\lambda) \cap (S^{n-1} \times B^1))$ to S^{n-1} have $q \circ \eta'(T) \cap C$ tamely embedded in S^{n-1} . All this entails is a controlled PL approximation so that, for each simplex σ of some triangulation of T , $q \circ \eta'(\sigma)$ is a simplex in S^{n-1} . This forces the 0-dimensional set $q \circ \eta'(T) \cap C$ to be standardly embedded in $\lambda(S^{n-1} \times [0, 1])$. It follows as in [Da4, §28] that $Sp(\lambda, q \circ \eta'(T) \cap C) \cong (q \circ \eta'(T) \cap C) \times B^2$ is 1-LCC embedded in $S^{n-1} \times R^2$. This means that we can regard $(q \circ \eta'(T) \cap C) \times B^2$ as the collection of disks corresponding to $C' \times B^2 \rightarrow S^{n-1} \times R^2$, where $C' \subset S^{n-1}$ is a standardly embedded 0-dimensional subset. Here it is easy to produce a map f of $S^{n-1} \times R^2$ to itself such that

$$(3.5.1) \quad f|_{\eta'(T)} = \text{identity},$$

$$(3.5.2) \quad f \text{ is one-to-one over } S^{n-1} \times R^2 \setminus \eta'(T),$$

$$(3.5.3) \quad f \text{ is } \mathcal{U} \text{-close to the identity,}$$

and

$$(3.5.4) \quad g \cap \eta'(T) \neq \emptyset \quad (g \in \mathcal{G}^+) \text{ implies } f(g) = g \cap \eta'(T).$$

Now the cell-like map $\pi^+ \circ f^{-1}: S^{n-1} \times R^2 \rightarrow S^{n-1} \times R^2/\mathcal{G}^+$ is 1-1 over $\pi^+ \circ f^{-1} \eta'(T)$. Since $(S^{n-1} \times R^2/\mathcal{G}^+) \setminus \pi^+ \circ f^{-1}(\eta'(T) \cap Sp(\lambda, C))$ is a manifold, it is a direct consequence of Edwards's work [E2] that $\pi^+ \circ f^{-1}$ can be approximated by a homeomorphism $h: S^{n-1} \times R^2 \rightarrow S^{n-1} \times R^2/\mathcal{G}^+$ subject to the conditions required in the theorem.

The following corollary necessary in §2 follows trivially.

Corollary 3.4. *Theorem 3.3 holds if $S^{n-1} \times \mathbb{R}^2$ is replaced by U where U is any π^+ -saturated open subset of $S^{n-1} \times \mathbb{R}^2$.*

4. PERFECT SUBGROUPS OF FINITELY PRESENTED GROUPS

The study of crumpled laminations leads us directly to the study of perfect subgroups of finitely presented groups since whenever (W, M, N, p) is a crumpled lamination, necessarily $\ker(i_\#)$ is perfect where $i: M \hookrightarrow W$ is inclusion [DT2, Lemma 2.5].

In [H], Howie classifies countable groups according to properties of their perfect subgroups. We warn the reader that these definitions are given as negations of particular properties and, as such, may be somewhat confusing. However, these are convenient for stating the behavior of the classes under the standard group theoretic operations. All groups are countable.

Definition 4.1. A group G belongs to $\mathcal{U}$ if G contains no nontrivial finitely generated perfect subgroups.

Definition 4.2. A group G belongs to $\mathcal{F}$ if G contains no nontrivial perfect subgroups.

Those groups which belong to $\mathcal{F}$ are precisely the transfinite metaabelian groups. Obviously, $\mathcal{F} \subset \mathcal{U}$. We introduce and investigate two intermediate classes of groups. These arise naturally out of the study of crumpled laminations.

Definition 4.3. A group G belongs to $\mathcal{L}$ if whenever (W, M, N, p) is a crumpled lamination, $i: M \hookrightarrow W$ is inclusion, and $\pi_1(M) = G$, then necessarily $\ker(i_\#) = 1$.

Consequently, crumpled laminations whose elements have fundamental groups belonging to $\mathcal{L}$ are trivial in the sense that the manifolds, W , involved are either products or nontrivial h -cobordisms [DT2, Theorem 5.1].

By the remark opening this section, $\mathcal{F} \subset \mathcal{L}$. For any finitely presented group G with nontrivial finitely generated perfect subgroup P , Daverman and Tinsley exhibit a crumpled lamination (W, M, N, p) with $\pi_1(M) \cong G$, $\pi_1(N) \cong G/\langle P \rangle$, and $\ker(i_\#) \cong \text{ncl}(P, G)$. As a result, $\mathcal{L} \subset \mathcal{U}$ and, thus, $\mathcal{F} \subset \mathcal{L} \subset \mathcal{U}$. In fact, W is constructed as the union of the mapping cylinder of an acyclic map on M and a possibly nontrivial h -cobordism. The nontrivial point preimages of the acyclic map may be chosen to be acyclic 2-complexes.

In this paper we have constructed a crumpled lamination which is fundamentally different. In particular, $\ker(i_\#)$ is not the normal closure of a finitely generated perfect group and W does not have a mapping cylinder structure of the type described above [T].

Definition 4.4. A group G belongs to $\mathcal{A}$ if for every almost acyclic group, H , and homomorphism, $\phi: H \rightarrow G$, with

$$\phi(H) < \text{ncl}(\phi(\text{Wild}(H)), G)$$

it is necessarily the case that $\phi(H) = 1$.

Since acyclic 2-complexes are trivially almost acyclic, we have $\mathcal{A} \subset \mathcal{U}$. In Theorem 2.0 we showed that $\mathcal{L} \subset \mathcal{A}$, so $\mathcal{F} \subset \mathcal{L} \subset \mathcal{A} \subset \mathcal{U}$.

Our efforts to find interesting examples of crumpled laminations has focused on the following question.

Question 4.5. Which of these containments are proper?

In [H] Howie shows that the containment $\mathcal{F} \subset \mathcal{U}$ is proper. In particular, Adams's group [Ad],

$$A = \langle y, t | y = y^{-1}t^{-1}y^{-1}tyt^{-1}yt \rangle$$

belongs to $\mathcal{U} - \mathcal{F}$. However, it is unknown whether $A \in \mathcal{L}$. Until recently, no other definitive information about the properness of these containments was available.

A reasonable approach to Question 4.5 studies the behavior of these four classes with respect to basic group theoretic operations of taking a free product (Free), a split amalgamated free product (SplitAmalg), and a split HNN extension (SplitHNN) Howie has done this for the two classes $\mathcal{F}$ and $\mathcal{U}$. We summarize his results for these two classes in table (4.1). Each row corresponds to an operation; each column corresponds to one of the classes. Each entry (yes/no) indicates whether the given class is closed under the corresponding operation.

	$\mathcal{F}$	$\mathcal{U}$
(4.1) Free	Yes	Yes
SplitAmalg	Yes	Yes
SplitHNN	No	Yes

Adams's group, A , can be presented:

$$A = \langle y, x, t | y = [y, x], x = y^t \rangle$$

so that A is a split HNN extension of the group

$$\langle y, x | y = [y, x] \rangle = \langle y, x | y^2 = y^x \rangle$$

and the latter is a split HNN extension of $\mathbb{Z}$. But $\text{ncl}(y, A)$ is a nontrivial perfect subgroup of A so $\mathcal{F}$ is not closed under the operation of taking split HNN extensions. As $\mathcal{U}$ is closed in this respect, $A \in \mathcal{U} - \mathcal{F}$.

Consider the group

$$(4.2) \quad G = \langle y, t | y = [y, y^{(y^t)}] \rangle.$$

In our introduction we indicated why $G \notin \mathcal{A}$ and how G is a split HNN extension of A and, thus, is the result of a finite number of split HNN extensions of $\mathbb{Z}$. So, neither $\mathcal{L}$ nor $\mathcal{A}$ is closed under split HNN extensions. But $\mathcal{U}$ is closed with respect to this operation. We summarize this in row 3 of table (4.3).

We show below that $\mathcal{A}$ is closed under split amalgamated products. A similar theorem for $\mathcal{L}$ is unresolved. The difficulty highlights the limit of our understanding of the relationship between the geometry of crumpled laminations and the structure of the fundamental groups of the involved manifolds.

All classes are closed under free products. To summarize,

	$\mathcal{F}$	$\mathcal{L}$	$\mathcal{A}$	$\mathcal{U}$
(4.3) Free	Yes	Yes	Yes	Yes
SplitAmalg	Yes	?	Yes	Yes
SplitHNN	No	No	No	Yes

The following lemma holds for both $\mathcal{L}$ and $\mathcal{A}$. For $\mathcal{L}$, we let $P = \ker(i_\#)$ where $i: M \mapsto W$. For $\mathcal{A}$, we let $P = \text{ncl}(\phi(H), G)$. In both cases P is a perfect normal subgroup of G .

Lemma 4.6. *Suppose $G \notin \mathcal{L}$ (resp. $\mathcal{A}$) and $\psi: G \mapsto G_1$ is a homomorphism so that $\psi(P) \neq 1 \in G_1$. Then $G_1 \notin \mathcal{L}$ (resp. $\mathcal{A}$).*

Proof. We consider the two cases separately. First, we have

$$(4.4) \quad 1 \neq \psi(P) = \psi(\text{ncl}(\phi(H), G)) < \text{ncl}(\psi \circ \phi(H), G_1).$$

Thus, $\psi \circ \phi(H) \neq 1$. Similarly,

$$(4.5) \quad \psi \circ \phi(H) < \psi(\text{ncl}(\phi(\text{Wild}(H))), G) < \text{ncl}(\psi \circ \phi(\text{Wild}(H)), G_1)$$

implying that $G_1 \notin \mathcal{A}$, finishing the first case.

Since $\mathcal{L}$ is not as yet understood in group theoretic terms, the proof is rather geometric. Let (W, M, N) be a nontrivial crumpled lamination with $\pi_1(M) = G$ and $\psi: G \mapsto G_1$ a surjection with $\psi(P) \neq 1$. Let $p: W \mapsto [0, 1]$ be the decomposition map. Let $B^2 = [0, 1] \times [0, 1]$, $tB^2 = [0, t] \times [0, t]$, and $W' = W \times [0, 2] \times [0, 2]$. For $0 \leq t \leq 1$ define

$$(4.6) \quad h_t = (p^{-1}(t) \times (1+t)B^2) \cup (p^{-1}([0, t]) \times \text{bdy}((1+t)B^2))$$

and $q': W' \mapsto [0, 1]$ by $q(h_t) = t$. Double W' along $M \times \text{clos}(2B^2 - B^2)$. The map q' naturally doubles to a map q'' from the double to $[0, 1]$. This yields a cobordism (W'', M'', N'') and a crumpled lamination $q'': W'' \mapsto [0, 1]$ with

$$(4.7.1) \quad \dim(W'') = n + 3,$$

$$(4.7.2) \quad M'' = q''^{-1}(0) \cong M \times S^2,$$

$$(4.7.3) \quad N'' = q''^{-1}(1) \cong N \times S^2.$$

The point of this construction is that there is a flat embedding of $M \times B^2 \times [0, 1]$ in W'' with $q''(M \times B^2 \times t) = t$. There are a finite number of 2-handles which may be attached to M to realize the surjective homomorphism ψ . These attachments naturally extend to $M \times B^2 \times [0, 1]$ to yield a crumpled lamination (W_1, M_1, N_1) with $\pi_1(M_1) \cong G_1$. Since $\psi(P) \neq 1 \in G_1$, this crumpled lamination is nontrivial, and, thus, $G_1 \notin \mathcal{L}$. This completes the proof of the lemma.

Theorem 4.7. *The class $\mathcal{A}$ is closed under the operation of taking split-amalgamated products.*

Proof. Suppose $G_1, G_2 \in \mathcal{A}$, $G = G_1 *_K G_2$, and $r: G_1 \mapsto K$ is the splitting retraction homomorphism. Then r extends to a retraction $s: G \mapsto G_2$. If $G \notin \mathcal{L}$ (resp. $\mathcal{A}$), then necessarily $1 \neq \phi(H) < P < \ker(s)$ or else $G_2 \notin \mathcal{L}$ (resp. $\mathcal{A}$). Any standard subgroup theorem for a free product with amalgamation (e.g., [LS]) gives the structure of $\phi(H)$ as the free product $F * (\Pi(\phi(H) \cap G_1^\lambda))$ where F is a free group and λ ranges over a subset of G . Let $\rho_\lambda: \phi(H) \mapsto \phi(H) \cap G_1^\lambda$ be the natural retraction. Since $G_1^\lambda \cong G_1 \in \mathcal{A}$, then $\phi(H) \cap G_1^\lambda = 1$. So, $\phi(H) = F$. But $\phi(\text{Wild}(H)) < \text{Wild}(\phi(H)) = 1$. Thus, $\phi(H) = 1$ and $G \in \mathcal{A}$.

The proof of Theorem 4.7 yields

Corollary 4.8. *The class $\mathcal{L}$ is closed under the operation of taking doubly split amalgamated products.*

Proof. There is also a retraction $s' : G \mapsto G_1$. The subgroup theorem then puts the perfect group P in a free subgroup of $G_1 *_K G_2$, forcing P to be trivial, and the conclusion follows.

Corollary 4.9. *Both $\mathcal{L}$ and $\mathcal{A}$ are closed under free products.*

APPENDIX: GENERALIZED n -MANIFOLDS

We examine the construction of §1 more closely. Let M be an orientable n -manifold ($n \geq 5$), $K \subset \text{int}(M)$ be a tamely embedded almost acyclic 2-complex, and L be a manifold mapping cylinder neighborhood of K in $\text{int}(M)$. All homology and cohomology is with $\mathbb{Z}$ coefficients. We denote the direct sum of s copies of $\mathbb{Z}$ by $\mathbb{Z}^s$. By definition we have, for some non-negative integer, s ,

$$(A.1) \quad H_q(L) \cong H_q(K) = \begin{cases} 0, & q \geq 2, \\ \mathbb{Z}^s, & q = 1, \\ \mathbb{Z}, & q = 0. \end{cases}$$

We also have the following equivalences:

$$(A.2) \quad H_q(M, M - K) \cong H_q(L, L - K) \cong H_q(L, \text{bdy}(L)) \cong H_{n-q}(L).$$

The first is by excision, the second by regular neighborhood theory, and the last by duality. So,

$$(A.3) \quad H_q(M, M - K) \cong \begin{cases} 0, & q \leq n - 2 \text{ or } q > n, \\ \mathbb{Z}^s, & q = n - 1, \\ \mathbb{Z}, & q = n. \end{cases}$$

Consider the exact sequence of $(L, \text{bdy}(L))$:

$$(A.4) \quad \begin{array}{ccccccc} \tilde{H}_{q+1}(L) & \rightarrow & H_{q+1}(L, \text{bdy}(L)) & \rightarrow & \tilde{H}_q(\text{bdy}(L)) & \rightarrow & \tilde{H}_q(L) \rightarrow H_q(L, \text{bdy}(L)) \\ \parallel & & \parallel & & \parallel & & \parallel \\ 0 & & 0 & & 0 & & H_q(M, M - K) \\ (q+1 \geq 2) & & (q+1 \leq n-2) & & (q \geq 2) & & \parallel \\ & & & & & & 0 \\ & & & & & & (q \leq n-2) \end{array}$$

Inspection yields

$$(A.5) \quad \tilde{H}_q(\text{bdy}(L)) \cong \begin{cases} \mathbb{Z}, & q = n - 1, \\ \mathbb{Z}^s, & q = n - 2, \\ \mathbb{Z}^s, & q = 1, \\ 0, & \text{otherwise,} \end{cases}$$

as long as $n \geq 4$.

Consider the identification spaces L/K and M/K and let $x = |K|$. Obviously, L/K is an AR and has trivial reduced homology. M/K is an ANR; it follows from the exact sequence of $(L/K, L/K - x)$ that $H_q(L/K, L/K - x) \cong \tilde{H}_{q-1}(L/K - x)$ and from regular neighborhood theory that the latter is isomorphic to $\tilde{H}_{q-1}(\text{bdy}(L))$. This and excision yield

$$(A.6) \quad H_q(M/K, M/K - x) \cong \tilde{H}_{q-1}(\text{bdy}(L)).$$

The grope construction of §1 produces a cell-like map, $d: (Y, y) \mapsto (M/K, x)$, where $W = d^{-1}(x)$ is a wedge of arcs with wedgepoint y , Y is an ANR, and $Y - y$ is a manifold. In the manifold, $Y - y$, duality gives

$$(A.7) \quad H_q(Y - y, Y - W) \cong H_c^{n-q}(W - y) = 0$$

so the homology sequence of the triple $(Y, Y - y, Y - W)$ shows that

$$(A.8) \quad H_q(Y, Y - W) \cong H_q(Y, Y - y).$$

But $d: (Y, Y - W) \mapsto (M/K, M/K - x)$ is a homology equivalence so (A.5), (A.6), and (A.8) imply

$$(A.9) \quad H_q(Y, Y - y) \cong \tilde{H}_{q-1}(\text{bdy}(L)) \cong \begin{cases} \mathbb{Z}, & q = n, \\ \mathbb{Z}^s, & q = n - 1, \\ \mathbb{Z}^s, & q = 2, \\ 0, & \text{otherwise.} \end{cases}$$

The construction of §1 also identifies a wedge of 2-spheres, $S = \bigvee_{j=1}^s S_j^2 \subset Y$ with wedgepoint y , with each S_j^2 representing a distinct generator of $H_2(Y, Y - y)$. Inspection of the following diagram shows that the homology sequence of $(Y, Y - y)$ splits at $H_2(Y)$:

$$(A.10) \quad \begin{array}{ccccccc} & & 0 & & & & 0 \\ & & \parallel & & & & \parallel \\ & & H_2(S - y) & \longrightarrow & H_2(S) & \xrightarrow{\cong} & H_2(S, S - y) & \longrightarrow & H_1(S - y) \\ & & \downarrow & & \downarrow 1:1 & & \downarrow \cong & & \downarrow \\ H_3(Y, Y - y) & \longrightarrow & H_2(Y - y) & \longrightarrow & H_2(Y) & \xrightarrow{\gamma} & H_2(Y, Y - y) & \longrightarrow & H_1(Y - y) \\ & & \parallel & & & & & & \\ & & 0 & & & & & & \end{array}$$

Thus, (A.9) and (A.10) force

$$(A.11) \quad H_2(Y) \cong H_2(Y - y) \oplus H_2(Y, Y - y) \cong H_2(Y - y) \oplus \mathbb{Z}^s.$$

Let $\delta: Y \mapsto Y/S$ be the identification map and let $Z = Y/S$ and $z = |S|$. The goal of this appendix is to show that Z is a homology manifold, i.e.,

$$(A.12) \quad H_q(Z, Z - z) \cong \begin{cases} \mathbb{Z}, & q = n, \\ 0, & q \neq n. \end{cases}$$

First, note that $\tilde{H}_q(Z) = \tilde{H}_q(Y/S) \cong H_q(Y, S)$. The exact homology sequence for the pair, (Y, S) yields $H_q(Y) \cong H_q(Y, S)$ ($q \neq 2$). For $q = 2$ we have shown (A.10) that the inclusion $S \mapsto Y$ induces a splitting at the level of second homology so

$$(A.13) \quad H_2(Y) \cong H_2(S) \oplus H_2(Y, S) \cong \mathbb{Z}^s \oplus H_2(Y, S)$$

and (A.11) and finitely generated abelian group theory show

$$(A.14) \quad H_2(Y, S) \cong H_2(Y - S).$$

Now, decompose S as $S = Q_1 \cup Q_2$ where Q_1 is a wedge of s closed 2-disks, Q_2 is a disjoint union of s closed 2-disks, and $Q_1 \cap Q_2$ is a disjoint union

of s simple closed curves. Duality applies [Do, Chapter VIII, §7] to give the Mayer-Vietoris sequence

$$(A.15) \quad \begin{array}{ccccccc} H_q(Y, Y-S) & \rightarrow & H_q(Y, Y-Q_1) \oplus H_q(Y, Y-Q_2) & \rightarrow & H_q(Y, Y-Q_1 \cap Q_2) & \rightarrow & \\ & & \uparrow \cong & & \uparrow \cong & & \\ & & H_q(Y, Y-y) \oplus H_q(\mathbb{R}^n, \mathbb{R}^n-A) & & H_q(\mathbb{R}^n, \mathbb{R}^n-B) & & \end{array}$$

where A and B are finite sets of s points and simple closed curves respectively. Then (A.9) and a diagram chase show that

$$(A.16) \quad H_q(Y, Y-S) \cong \begin{cases} \mathbb{Z}, & q = n, \\ \mathbb{Z}^s, & q = 2, \\ 0, & \text{otherwise.} \end{cases}$$

Finally, $\delta: (Y, Y-S) \mapsto (Z, Z-z)$ induces the diagram

$$(A.17) \quad \begin{array}{ccccccc} H_{q+1}(Y, Y-S) & \longrightarrow & H_q(Y-S) & \xrightarrow{\cong(n-2 \geq q \geq 3)} & H_q(Y) & \longrightarrow & H_q(Y, Y-S) \\ \delta_* \downarrow & & \delta_* \downarrow \cong & & \delta_* \downarrow \cong_{(q \neq 2)} & & \delta_* \downarrow \\ H_{q+1}(Z, Z-z) & \longrightarrow & H_q((Z-z)) & \longrightarrow & H_q(Z) & \longrightarrow & H_q(Z, Z-z) \end{array}$$

It is immediate that

$$(A.18) \quad H_q(Z, Z-z) \cong \begin{cases} \mathbb{Z}, & q = n, \\ 0, & n-2 \geq q \geq 4. \end{cases}$$

The cases $q = n-1, 3, 2$, or 1 follow from careful diagram chases using (A.14) and (A.16).
