DIRICHLET PROBLEM AT INFINITY FOR HARMONIC MAPS: RANK ONE SYMMETRIC SPACES

HAROLD DONNELLY

ABSTRACT. Given a symmetric space M , of rank one and noncompact type, one compactifies M by adding a sphere at infinity, to obtain a manifold M' with boundary. If $\bar{M}$ is another rank one symmetric space, suppose that $f: \partial M' \rightarrow \partial \bar{M}'$ is a continuous map. The Dirichlet problem at infinity is to construct a proper harmonic map $u: M \rightarrow \bar{M}$ with boundary values f . This paper concerns existence, uniqueness, and boundary regularity for this Dirichlet problem.

1. INTRODUCTION

Let M and $\bar{M}$ be complete simply connected manifolds of strictly negative curvature. One may compactify M and $\bar{M}$, using asymptotic classes of geodesic rays, by adding spheres at infinity. We denote the compactifications by M' and $\bar{M}'$, and the spheres added at infinity by $\partial M'$, $\partial \bar{M}'$. Suppose that $f: \partial M' \rightarrow \partial \bar{M}'$ is a continuous map. The Dirichlet problem at infinity consists of finding a harmonic map $u: M \rightarrow \bar{M}$, with boundary values f at infinity. Here one means that $u \in C^2(M, \bar{M}) \cap C^0(M', \bar{M}')$, and the boundary values f are taken continuously. In general, the Dirichlet problem at infinity seems to be quite difficult. If M and $\bar{M}$ both have constant negative curvature, then Li and Tam [8, 9] have proved a number of significant results, concerning uniqueness, existence, and boundary regularity. Our plan is to extend this discussion to the context of rank one symmetric spaces.

Suppose now that M and $\bar{M}$ are rank one symmetric spaces of noncompact type. In the unbounded model, M is realized as $R^+ \times N$, where R^+ is the positive real line and N is a two term nilpotent group. The Lie algebra of N decomposes as $\mathfrak{n} = \mathfrak{n}_1 \oplus \mathfrak{n}_2$, where $\mathfrak{n}_2$ is central in $\mathfrak{n}$ and $[\mathfrak{n}_1, \mathfrak{n}_1] \subset \mathfrak{n}_2$. For the exceptional case, of constant negative curvature on M , we adopt the convention that $\mathfrak{n}_1$ is the entire abelian Lie algebra and $\mathfrak{n}_2$ is empty. In the unbounded model $R^+ \times N$, the metric of M is realized as a doubly warped product [1]:

$$(1.1) \quad g_M = \left(\frac{dy}{y} \right)^2 + y^{-2} g_{\mathfrak{n}_1} + y^{-4} g_{\mathfrak{n}_2}.$$

Here $y \in R^+$ is the coordinate on the first factor of $R^+ \times N$. Via Cayley transform, this provides local coordinate charts at the boundary $\partial M'$ of the compactification. Of course, the same discussion applies to $\overline{M}'$. To formulate our results, we introduce indices $0 \leq j \leq n_1 + n_2$. The index 0 refers to $\partial/\partial y$, the indices $1 \leq j \leq n_1$ allude to the g_{n_1} part of (1.1); and the indices $n_1 + 1 \leq j \leq n_1 + n_2$ refer to the g_{n_2} part of (1.1). On $\overline{M}$, we use corresponding Greek indices $0 \leq \alpha \leq \bar{n}_1 + \bar{n}_2$.

Our first observation is that if f is the boundary value of a harmonic map $u \in C^2(M, \overline{M}) \cap C^1(M', \overline{M}')$, then $f_j^\gamma = 0$, $1 \leq j \leq n_1$, $\bar{n}_1 + 1 \leq \gamma \leq \bar{n}_1 + \bar{n}_2$. Here f_j^γ are the components of the differential of f . By contrast, Li and Tam [8] proved that, for spaces of constant negative curvature, any f with nonvanishing energy density can occur as the boundary value of a $C^1(M', \overline{M}')$ harmonic map. If h is a harmonic self-map of the unit ball in C^n , with its Bergman metric, the condition $f_j^\gamma = 0$ means that f is a contact transformation.

We now describe our uniqueness results. Suppose that both h and $\hat{h}$ are proper harmonic maps between rank one symmetric space M and $\overline{M}$. Assume $h, \hat{h} \in C^2(M', \overline{M}')$ have the same boundary value $f: \partial M' \rightarrow \partial \overline{M}'$, which satisfies

$$\sum_{j=n_1+1}^{n_1+n_2} \sum_{\gamma=\bar{n}_1+1}^{\bar{n}_1+\bar{n}_2} f_j^\gamma f_j^\gamma > 0.$$

Then h and $\hat{h}$ are identical. If the range $\overline{M}$ has constant negative curvature, then one only needs $h, \hat{h} \in C^1(M', \overline{M}')$. If the common boundary value satisfies

$$\sum_{j=1}^{n_1} \sum_{\gamma=1}^{\bar{n}_1} f_j^\gamma f_j^\gamma > 0$$

then $h = \hat{h}$. This last result was proved by Li and Tam in [8] when both M and $\overline{M}$ have constant negative curvature, and their proof is similar to ours.

Our basic existence result assumes that one is given boundary data $f \in C^{2,\varepsilon}(\partial M', \partial \overline{M}')$, $0 < \varepsilon < 1$, so that $f_j^\gamma = 0$, $1 \leq j \leq n_1$, $\bar{n}_1 + 1 \leq \gamma \leq \bar{n}_1 + \bar{n}_2$, and $\sum_{j=n_1+1}^{n_1+n_2} \sum_{\gamma=\bar{n}_1+1}^{\bar{n}_1+\bar{n}_2} f_j^\gamma f_j^\gamma > 0$. We construct a harmonic map $u: M \rightarrow \overline{M}$, which assumes the boundary values f continuously. If the range $\overline{M}$ has constant negative curvature, it is enough to assume $f \in C^{1,\varepsilon}(\partial M', \partial \overline{M}')$, $0 < \varepsilon < 1$, and $\sum_{j=1}^{n_1} \sum_{\gamma=1}^{\bar{n}_1} f_j^\gamma f_j^\gamma > 0$. We prove the existence of a harmonic map u , which assumes the boundary values f continuously. If both the domain and range have constant negative curvature, this again reduces to a result of [8], where similar arguments were employed.

For our regularity results, we assume that $f \in C^{l+2,\varepsilon}(\partial M', \partial \overline{M}')$, $0 \leq l < n_1 + 2n_2$, $0 < \varepsilon < 1$, satisfies $f_j^\gamma = 0$, $1 \leq j \leq n_1$, $\bar{n}_1 + 1 \leq \gamma \leq \bar{n}_1 + \bar{n}_2$, and $\sum_{j=n_1+1}^{n_1+n_2} \sum_{\gamma=\bar{n}_1+1}^{\bar{n}_1+\bar{n}_2} f_j^\gamma f_j^\gamma > 0$. We prove that there is a harmonic map, $u: M \rightarrow \overline{M}'$, $u \in C^{k+1,\bar{\varepsilon}}(M', \overline{M}') \cap C^2(M, \overline{M})$, with boundary values f , when $\bar{\varepsilon} < \varepsilon$ and $-2 \leq 2k < l - 1$. Although the factor 2 in $2k$ is not appealing, it may be needed. In [4], Graham studied the model linear problem of the Bergman Laplacian on the unit ball in C^n , where similar difficulties appear. If both M

and $\overline{M}$ have constant negative curvature, then one instead assumes that $f \in C^{l+1, \varepsilon}(\partial M', \partial \overline{M}')$, $0 < \varepsilon < 1$, $0 \leq l < n_1$, and $\sum_{j=1}^{n_1} \sum_{\gamma=1}^{\overline{n}_1} f_j^\gamma f_j^\gamma > 0$. Then there exists a harmonic map $u: M \rightarrow \overline{M}$, $u \in C^{l+1, \varepsilon}(M', \overline{M}') \cap C^2(M, \overline{M})$, with boundary values f . This was proved earlier in [8]. However, our method of proof is somewhat different. We replace the use of conformality to the Euclidean Laplacian with ideas based upon the facts that our spaces M , $\overline{M}$ admit transitive isometry groups.

2. TENSION IN AN ADAPTED FRAME FIELD

Let $h: M \rightarrow \overline{M}$ be a C^2 map between Riemannian manifolds M and $\overline{M}$. The differential dh may be regarded as a section of $T^*M \otimes h^{-1}T\overline{M}$. The bundle $T^*M \otimes h^{-1}T\overline{M}$ admits a connection ∇ induced by the Levi-Civita connection on M and the pull-back of the Levi-Civita connection on $\overline{M}$. One defines the tension $\tau(h) = \text{Tr}(\nabla dh)$. For later reference, we compute $\tau(h)$ explicitly, especially in the case where M and $\overline{M}$ are rank one symmetric spaces of noncompact type.

Suppose that e_i is a local frame field on TM , with dual coframe field e_i^* , $i = 1, 2, \dots, \dim M$. Let f_α be a local frame field for $T\overline{M}$, $\alpha = 1, 2, \dots, \dim \overline{M}$. We do not assume that either e_i or f_α is orthonormal. We may denote the differential of h as $dh = h_i^\alpha e_i^* \otimes f_\alpha$, where one sums over both the indices i and α . Let $g^{ij} = \langle e_i^*, e_j^* \rangle$ and $h_{ij}^\alpha = e_j h_i^\alpha$. Calculating from the definition yields

$$\begin{aligned} \tau(h) &= \text{Tr}(\nabla dh) = \text{Tr}(e_j^* \otimes \nabla_{e_j}(h_i^\alpha e_i^* \otimes f_\alpha)) \\ &= g^{ij} h_{ij}^\alpha f_\alpha + h_i^\alpha \langle e_j^*, \nabla_{e_j} e_i^* \rangle f_\alpha + h_i^\alpha g^{ij} \nabla_{e_j} f_\alpha \end{aligned}$$

where summation is understood over i , j , and α .

We rewrite the formula for $\tau(h)$ by noting that

$$\begin{aligned} \langle e_j^*, \nabla_{e_j} e_i^* \rangle &= g^{jk} e_k(\nabla_{e_j} e_i^*) = -g^{jk} e_i^*(\nabla_{e_j} e_k), \\ \nabla_{e_j} f_\alpha &= \nabla_{h_j^\beta f_\beta} f_\alpha = h_j^\beta \nabla_{f_\beta} f_\alpha = h_j^\beta f_\gamma^*(\nabla_{f_\beta} f_\alpha) f_\gamma. \end{aligned}$$

Thus $\tau(h) = \tau^\alpha(h) f_\alpha$, where

$$(2.1) \quad \tau^\alpha(h) = g^{ij} h_{ij}^\alpha - g^{jk} e_i^*(\nabla_{e_j} e_k) h_i^\alpha + g^{ij} h_j^\gamma h_i^\beta f_\alpha^*(\nabla_{f_\beta} f_\gamma).$$

The summation convention is employed for the indices i , j , k , β , and γ .

The next step is to give more explicit expressions for $\tau(h)$ in the special case where M on $\overline{M}$ are both rank one symmetric spaces of noncompact type. In the unbounded model, M is realized as $R^+ \times N$, where R^+ is the positive real line and N is a two term nilpotent Lie group. The Lie algebra of N decomposes as $\mathfrak{n} = \mathfrak{n}_1 \oplus \mathfrak{n}_2$, where $\mathfrak{n}_2$ is the central in $\mathfrak{n}$ and $[\mathfrak{n}_1, \mathfrak{n}_1] \subset \mathfrak{n}_2$. The hyperbolic space of constant negative curvature is exceptional, and N reduces to the abelian group $R^{\dim M - 1}$. For the hyperbolic space, we adopt the convention that $\mathfrak{n}_1$ is the entire abelian Lie algebra and $\mathfrak{n}_2$ is empty. Choose an orthonormal basis $X_1, X_2, \dots, X_{n_1}$ for $\mathfrak{n}_1$ and $Z_1, Z_2, \dots, Z_{n_2}$ for $\mathfrak{n}_2$, relative to a left invariant metric on N . Here $n_1 = \dim \mathfrak{n}_1$, $n_2 = \dim \mathfrak{n}_2$, and thus $\dim M = n_1 + n_2 + 1$. One has $[X_i, Z_j] = [Z_j, Z_k] = 0$ and $[X_i, X_j] = a_{ij}^k Z_k$, for some structure constants a_{ij}^k . A sum is understood over k . In the

unbounded model $R^+ \times N$, the metric of M is realized as a doubly warped product [1]:

$$(2.2) \quad g_M = \left(\frac{dy}{y} \right)^2 \oplus y^{-2} g_{n_1} \oplus y^{-4} g_{n_2}, \quad y > 0.$$

Here $y \in R^+$ is the coordinate on the first factor of $R^+ \times N$. Moreover, $g_{n_1} + g_{n_2}$ is a left invariant metric on N . Of course, the same discussion applies to $\bar{M}$, where we denote the corresponding quantities with a bar, for example $\bar{X}_i$ are an orthonormal basis of $\bar{n}_1$.

On any Riemannian manifold, with metric g , there is a standard elementary formula [6] for the Levi-Civita connection:

$$2g(A, \nabla_C B) = Cg(A, B) + Bg(A, C) - Ag(B, C) \\ + g(C, [A, B]) + g(B, [A, C]) - g(A, [B, C])$$

where A, B, C are vector fields. Using this formula, a lengthy but straightforward computation gives the connection ∇ , in the frame field $\partial/\partial y, X_i, Z_j$, of M :

$$(2.3) \quad \begin{aligned} \nabla_{\partial/\partial y} \frac{\partial}{\partial y} &= -y^{-1} \frac{\partial}{\partial y}, \\ \nabla_{X_i} \frac{\partial}{\partial y} &= \nabla_{\partial/\partial y} X_i = -y^{-1} X_i, \\ \nabla_{Z_i} \frac{\partial}{\partial y} &= \nabla_{\partial/\partial y} Z_i = -2y^{-1} Z_i, \\ \nabla_{X_i} X_j &= y^{-1} \delta_{ij} \frac{\partial}{\partial y} + \frac{1}{2} a_{ij}^k Z_k, \\ \nabla_{Z_i} Z_j &= 2y^{-3} \delta_{ij} \frac{\partial}{\partial y}, \\ \nabla_{X_i} Z_j &= \nabla_{Z_j} X_i = \frac{1}{2} y^{-2} a_{ki}^j X_k. \end{aligned}$$

In the exceptional case where M is the hyperbolic space, there are no Z_i 's, and (2.3) becomes

$$(2.3a) \quad \begin{aligned} \nabla_{\partial/\partial y} \frac{\partial}{\partial y} &= -y^{-1} \frac{\partial}{\partial y}, \\ \nabla_{X_i} \frac{\partial}{\partial y} &= \nabla_{\partial/\partial y} X_i = -y^{-1} X_i, \\ \nabla_{X_i} X_j &= y^{-1} \delta_{ij} \frac{\partial}{\partial y}. \end{aligned}$$

Of course, the frame field $\partial/\partial y, X_i, Z_j$ is orthogonal but not orthonormal for the metric g_M . Sometimes, it will be useful to employ the orthonormal

frame field $y\partial/\partial y$, yX_i , y^2Z_j , where one has the corresponding expressions

$$\begin{aligned}
 (2.4) \quad & \nabla_{y\partial/\partial y} \left(y \frac{\partial}{\partial y} \right) = 0, \\
 & \nabla_{yX_i} \left(y \frac{\partial}{\partial y} \right) - \nabla_{y\partial/\partial y} (yX_i) = \left[yX_i, y \frac{\partial}{\partial y} \right] = -yX_i, \\
 & \nabla_{y\partial/\partial y} (yX_i) = 0, \\
 & \nabla_{y^2Z_i} \left(y \frac{\partial}{\partial y} \right) - \nabla_{y\partial/\partial y} (y^2Z_i) = \left[y^2Z_i, y \frac{\partial}{\partial y} \right] = -2y^2Z_i, \\
 & \nabla_{y\partial/\partial y} (y^2Z_i) = 0, \\
 & \nabla_{yX_i} (yX_j) = \delta_{ij} y \frac{\partial}{\partial y} + \frac{1}{2} a_{ij}^k y^2 Z_k, \\
 & \nabla_{y^2Z_i} (y^2Z_j) = 2\delta_{ij} y \frac{\partial}{\partial y}, \\
 & \nabla_{yX_i} (y^2Z_j) = \nabla_{y^2Z_j} (yX_i) = \frac{1}{2} a_{ki}^j yX_k.
 \end{aligned}$$

The advantage of the orthonormal frame field $y\partial/\partial y$, yX_i , y^2Z_j lies in fact that the coefficients, on the right-hand side of (2.4), are independent of y . Also, for the hyperbolic space, (2.4) becomes

$$\begin{aligned}
 (2.4a) \quad & \nabla_{y\partial/\partial y} \left(y \frac{\partial}{\partial y} \right) = 0, \\
 & \nabla_{yX_i} \left(y \frac{\partial}{\partial y} \right) - \nabla_{y\partial/\partial y} (yX_i) = \left[yX_i, y \frac{\partial}{\partial y} \right] = -yX_i, \\
 & \nabla_{y\partial/\partial y} (yX_i) = 0, \\
 & \nabla_{yX_i} (yX_j) = \delta_{ij} y \frac{\partial}{\partial y}.
 \end{aligned}$$

Returning to the local expression for the tension field, we choose the frame field e_i on M to consist of $e_0 = \partial/\partial y$; $e_i = X_i$, $1 \leq i \leq n_1$; $e_i = Z_{i-n_1}$, $n_1 + 1 \leq i \leq n_1 + n_2$. Similarly, on $\bar{M}$ it is natural to select $f_0 = \partial/\partial \bar{y}$; $f_\alpha = \bar{X}_\alpha$, $1 \leq \alpha \leq \bar{n}_1$; $f_\alpha = \bar{Z}_{\alpha-\bar{n}_1}$, $\bar{n}_1 + 1 \leq \alpha \leq \bar{n}_1 + \bar{n}_2$. Using (2.1) and (2.3), we compute

$$\begin{aligned}
 (2.5) \quad & \tau^0(h) = g^{jj} h_{jj}^0 + (1 - n_1 - 2n_2) h_0^0 y - g^{jj} h_j^0 h_j^0 \bar{h}^{-1} \\
 & \quad + g^{jj} \sum_{j=1}^{\bar{n}_1} h_j^\gamma h_j^\gamma \bar{y}^{-1} + g^{jj} \sum_{j=\bar{n}_1+1}^{\bar{n}_1+\bar{n}_2} h_j^\gamma h_j^\gamma (2\bar{y}^{-3}), \\
 & \tau^\alpha(h) = g^{jj} h_{jj}^\alpha + (1 - n_1 - 2n_2) h_0^\alpha y - 2g^{jj} h_j^0 h_j^\alpha \bar{y}^{-1} \\
 & \quad + g^{jj} \sum_{\beta=1}^{\bar{n}_1} \sum_{\gamma=\bar{n}_1+1}^{\bar{n}_1+\bar{n}_2} \alpha_{\alpha\beta}^{\gamma-\bar{n}_1} h_j^\beta h_j^\gamma \bar{y}^{-2}, \quad 1 \leq \alpha \leq \bar{n}_1, \\
 & \tau^\alpha(h) = g^{jj} h_{jj}^\alpha + (1 - n_1 - 2n_2) h_0^\alpha y - 4g^{jj} h_j^0 h_j^\alpha \bar{y}^{-1}, \\
 & \quad \bar{n}_1 + 1 \leq \alpha \leq \bar{n}_1 + \bar{n}_2.
 \end{aligned}$$

Here j is summed from 0 to $n_1 + n_2$. Note that $\dim M = n_1 + n_2 + 1$. If the domain M is hyperbolic space, the formulas (2.5) hold with $n_2 = 0$. For $\bar{M}$

of constant negative curvature, we have the analogous formulas

$$\begin{aligned}
 \tau^0 &= g^{jj} h_{jj}^0 + (1 - n_1 - 2n_2) h_0^0 y - g^{jj} h_j^0 h_j^0 \bar{y}^{-1} \\
 (2.5a) \quad &+ g^{jj} \sum_{\gamma=1}^{\bar{n}_1} h_j^\gamma h_j^\gamma \bar{y}^{-1}, \\
 \tau^\alpha(h) &= g^{jj} h_{jj}^\alpha + (1 - n_1 - 2n_2) h_0^\alpha y - 2g^{jj} h_j^0 h_j^\alpha \bar{y}^{-1}, \quad 1 \leq \alpha \leq \bar{n}_1.
 \end{aligned}$$

3. NECESSARY CONDITIONS AND UNIQUENESS

Suppose that M is a simply connected, rank one, symmetric space of noncompact type. The exponential map, from any basepoint, provides a diffeomorphism between M and a Euclidean space with the dimension of M . One compactifies M by adding a sphere at infinity. The compactification M' of M is thus homeomorphic to a Euclidean ball of the same dimension as M . Moreover, this compactification M' admits the structure of a C^∞ manifold with boundary. The boundary coordinate charts are given by the Cayley transform. In such charts, the metric admits the representation (2.2), with the ideal boundary portion contained in $0 \times N$.

Let $h: M \rightarrow \bar{M}$ be a C^2 proper map between rank one symmetric spaces of noncompact type. Suppose that h extends to a C^1 map $h: M' \rightarrow \bar{M}'$ from the compactification M' of M , to the compactification $\bar{M}'$ of $\bar{M}$. We plan to investigate necessary conditions satisfied by the first derivatives of h at the boundary, when h is harmonic in the interior M . We begin with some preparatory lemmas:

Lemma 3.1. *Assume that V_j are n linearly independent C^∞ vector fields defined on a ball, centered at p , in n -dimensional Euclidean space. Given real numbers α_j , there exists a C^∞ function ψ so that $V_j \psi(p) = \alpha_j$ and $V_j V_j \psi(p) = 0$, for each fixed $j = 1, 2, \dots, n$.*

Proof. If x_k are local coordinates, then we may write $V_j = \sum_k a_{jk}(x)(\partial/\partial x_k)$, where a_{jk} is an invertible matrix. The first derivatives of ψ are determined by $\sum_k a_{jk}(p) \partial \psi(p) / \partial x_k = \alpha_j$, that is $\partial \psi(p) / \partial x_k = \sum a_{ks}^{-1}(p) \alpha_s$.

For the conditions on the second derivatives, one has

$$\begin{aligned}
 0 &= V_j V_j \psi(p) = \sum_k a_{jk} \frac{\partial}{\partial x_k} \sum_s a_{js} \frac{\partial \psi}{\partial x_s}, \\
 0 &= \sum_{k,s} a_{jk} a_{js} \frac{\partial^2 \psi}{\partial x_k \partial x_s} + \sum_k a_{jk} \frac{\partial a_{js}}{\partial x_k} \frac{\partial \psi}{\partial x_s}.
 \end{aligned}$$

Define

$$\beta_j = - \sum_k a_{jk} \frac{\partial a_{js}}{\partial x_k} \frac{\partial \psi}{\partial x_s},$$

evaluated at p . Let b denote a diagonal matrix with entries $b_{jj} = \beta_j$. The condition $V_j V_j \psi(p) = 0$ may be written as $(a(\text{Hess } \psi)a^t)_{jj} = b_{jj}$, where a^t is the transpose of a . It suffices to choose $\text{Hess } \psi = a^{-1}b(a^t)^{-1}$, a symmetric matrix.

We apply the preceding lemma in a coordinate chart centered at a boundary point p of the compactification M' of M . In the unbounded model the

metric is given by (2.2) and we may choose $p = (0, e) \in R \times N$, where e is the identity element in the group N . The collection of vector fields $V_j = e_j$ consists of $\partial/\partial y$, X_k , Z_l , with $1 \leq k \leq n_1$, $n_1 + 1 \leq l \leq n_1 + n_2$, and $0 \leq j \leq n_1 + n_2$. The Laplacian of M , acting on functions, has the form

$$\Delta\psi = \sum_j g^{jj} e_j e_j \psi + (1 - n_1 - 2n_2)y \frac{\partial\psi}{\partial y}.$$

More generally, if $\phi = \sum_i \phi_i e_i^*$ is a 1-form, then the divergence of ϕ is given by

$$\delta\phi = \sum_j g^{jj} e_j \phi_j + (1 - n_1 - 2n_2)y \phi_0.$$

If $\phi = d\psi$, then $\Delta\psi = \delta d\psi = \delta\phi$. Under the circumstances, one has

Lemma 3.2. *Suppose that $\phi \in C^1\Lambda^1 M \cap C^0\Lambda^1 M'$, is a 1-form defined on a neighborhood of $p \in M'$. If $\phi = \sum_i \phi_i e_i^*$, then there is a sequence of points $p_k \rightarrow p$, with $\sum_j g^{jj}(e_j \phi_j)y^{-1} \rightarrow 0$.*

Proof. If $\phi \in C^1\Lambda^1 M'$, the conclusion holds for any sequence converging to p , since $g^{jj} = O(y^2)$, $0 \leq j \leq n_1 + n_2$. Under the weaker hypothesis of the lemma, $\psi \in C^1\Lambda^1 M \cap C^0\Lambda^1 M'$, more argument is required. By Lemma 3.1, we may choose a C^∞ function ψ with $d\psi(p) = \phi(p)$ and $e_j e_j \psi(p) = 0$, for all $0 \leq j \leq n_1 + n_2$. let $p_k \rightarrow p$ be any sequence and use the symbol $B(p_k, 1)$ to denote the unit ball centered at p , relative to the complete metric (2.2).

By Stokes' theorem,

$$\int_{B(p_k, 1)} \delta\phi = \int_{\partial B(p_k, 1)} \phi(\nu) = \int_{\partial B(p_k, 1)} d\psi(\nu) + \varepsilon_1 y$$

where ν is a unit outward normal to $\partial B(p_k, 1)$. The symbols ε_i will denote quantities which become arbitrarily small as $p_k \rightarrow p$. The factor y appears because we measure the length of covectors in the invariant metric of the symmetric space.

Applying Stokes' theorem again,

$$\int_{B(p_k, 1)} \delta\phi = \int_{B(p_k, 1)} \Delta\psi + \varepsilon_1 y.$$

By Lemma 3.1,

$$\Delta\psi = (1 - n_1 - 2n_2)\phi \left(\frac{\partial}{\partial y} \right) + \varepsilon_2 y.$$

Consequently, by the formula for $\delta\phi$ given above,

$$\frac{1}{y} \int_{B(p_k, 1)} \sum_j g^{jj} e_j \phi_j \rightarrow 0, \quad \text{as } p_k \rightarrow p.$$

Since the balls $B(p_k, 1)$ have volume independent of k , there exists a sequence $q_k \in B(p_k, 1)$ satisfying the conclusion of Lemma 3.2.

We return to our map $h \in C^2(M, \overline{M}) \cap C^1(M', \overline{M}')$. Formula (2.5) gives the $\partial/\partial y$ component of the tension of h . If $\tau^0(h) = O(y^{-1+\varepsilon})$, then multiply the formula, (2.5), for $\tau^0(h)$ by $\bar{y}^3 y^{-2}$, and let $y \rightarrow 0$, to deduce

Condition 3.3. $\sum_{j=0}^{n_1} \sum_{\gamma=\bar{n}_1+1}^{\bar{n}_1+\bar{n}_2} h_j^\gamma h_j^\gamma = 0$, at the boundary.

Here, we applied Lemma 3.2 to $\phi = \sum h_j^0 e_j^*$, in order to eliminate the terms involving second derivatives. In particular, a notable special case is

Proposition 3.4. Suppose that $h: M \rightarrow \bar{M}$ is C^2 proper harmonic map which extends to a C^1 map $h: M' \rightarrow \bar{M}'$. Let $f: \partial M' \rightarrow \partial \bar{M}'$ be the boundary values of h . Then $\sum_{j=1}^{n_1} \sum_{\gamma=\bar{n}_1+1}^{\bar{n}_1+\bar{n}_2} f_j^\gamma f_j^\gamma = 0$.

If h is a harmonic self-map of the rank one Hermitian space, the unit ball in C^n with its Bergman metric, then Proposition 3.4 states that the boundary value of h is a contact transformation. This example is typical of the situation where the range is a rank one symmetric space, but not the hyperbolic space.

If $\bar{M}$ is hyperbolic, then Condition 3.3 is vacuous, and we now consider this situation. Suppose $h \in C^2(M, \bar{M}) \cap C^1(M', \bar{M}')$ and $\bar{M}$ has constant negative curvature. The formulas (2.5a) are now applicable. If $\tau^\alpha(h) = O(y^{1+\varepsilon})$, $\alpha \geq 0$, for some $\varepsilon > 0$, then multiply (2.5a) by $\bar{y}y^{-2}$ and let $y \rightarrow 0$ to deduce

$$\begin{aligned} (-n_1 - 2n_2)(h_0^0)^2 + \sum_{j=0}^{n_1} \sum_{\gamma=1}^{\bar{n}_1} h_j^\gamma h_j^\gamma &= 0, \\ (-1 - n_1 - 2n_2)h_0^\alpha h_0^0 &= 0, \quad \alpha \geq 1. \end{aligned}$$

Again, we employed Lemma 3.2 to handle the second order terms. Also, note that $h_j^0 = 0$ at the boundary, for $j \geq 1$, since $h: \partial M' \rightarrow \partial \bar{M}'$. It is easy to deduce

Condition 3.3a. If the range $\bar{M}$ has constant negative curvature and the boundary values f satisfy $\sum_{j=1}^{n_1} \sum_{\gamma=1}^{\bar{n}_1} f_j^\gamma f_j^\gamma > 0$, then, at the boundary,

$$h_0^0 = \left[\sum_{j=1}^{n_1} \sum_{\gamma=1}^{\bar{n}_1} \frac{f_j^\gamma f_j^\gamma}{n_1 + 2n_2} \right]^{1/2}; \quad h_0^\alpha = 0, \quad \alpha \geq 1.$$

This leads to the following uniqueness theorem.

Proposition 3.5. Let h and $\hat{h}$ be proper harmonic maps from the rank one symmetric space M to the hyperbolic space $\bar{M}$, of constant negative curvature. Assume that both h and $\hat{h}$ extend to maps in $C^1(M', \bar{M}')$. If $h, \hat{h}$ have the same boundary map $f: \partial M' \rightarrow \partial \bar{M}$, and $\sum_{j=1}^{n_1} \sum_{\gamma=1}^{\bar{n}_1} f_j^\gamma f_j^\gamma > 0$ then h and $\hat{h}$ are identical.

Proof. If both M and $\bar{M}$ are hyperbolic, this was proved by Li and Tam [8]. Their proof extends with only minor changes.

Consider again a proper map between arbitrary rank one symmetric spaces $M, \bar{M}$ of noncompact type. To proceed further, we make the additional assumption that our map h is C^2 up to the boundary of the compactification. If $\tau^0(h) = O(y^{1+\varepsilon})$, then Condition 3.3 holds, and we may multiply (2.5) by $\bar{y}^3 y^{-4}$, letting $y \rightarrow 0$ to give

Condition 3.6.

$$(n_1 + 2n_2)(h_0^0)^4 - \sum_{j=0}^{n_1} \sum_{\gamma=1}^{\bar{n}_1} h_j^\gamma h_j^\gamma (h_0^0)^2 - 2 \sum_{j=0}^{n_1} \sum_{\gamma=\bar{n}_1+1}^{\bar{n}_1+\bar{n}_2} h_{j0}^\gamma h_{j0}^\gamma - 2 \sum_{j=n_1+1}^{n_1+n_2} \sum_{\gamma=\bar{n}_1+1}^{\bar{n}_1+\bar{n}_2} h_j^\gamma h_j^\gamma = 0,$$

at the boundary.

Similarly, for $1 \leq \alpha \leq \bar{n}_1$, we suppose that $\tau^\alpha(h) = O(y^{1+\varepsilon})$. Multiplying (2.5) by $\bar{y}^2 y^{-3}$ and letting $y \rightarrow 0$ yields, assuming our previously established Condition 3.3:

Condition 3.7.

$$(1 + n_2 + 2n_2)h_0^\alpha (h_0^0)^2 - \sum_{j=0}^{n_1} \sum_{\beta=1}^{\bar{n}_1} \sum_{\gamma=\bar{n}_1+1}^{\bar{n}_1+\bar{n}_2} \alpha_{\alpha\beta}^{\gamma-\bar{n}_1} h_j^\beta h_{j0}^\gamma = 0,$$

at the boundary.

Finally, we consider $\bar{n}_1 + 1 \leq \alpha \leq \bar{n}_1 + \bar{n}_2$ and suppose that $\tau^\alpha(h) = O(y^{2+\varepsilon})$. Multiplying (2.5) by $\bar{y} y^{-3}$, using Condition 3.3, and letting $y \rightarrow 0$, gives

Condition 3.8. $(2 + n_1 + 2n_2)h_0^0 h_{00}^\alpha = 0$, at the boundary.

Note that $h_j^\alpha = 0$, along the boundary, by condition 3.3, for $1 \leq j \leq n_1$, $\bar{n}_1 + 1 \leq \alpha \leq \bar{n}_1 + \bar{n}_2$. Since e_j is tangent to the boundary, we also have $h_{jj}^\alpha = e_j h_j^\alpha = 0$, for such j and α .

To proceed further, we consider the integrability condition $ddh = 0$, which holds for any C^2 map h [2]. Recall that $dh = h_i^\alpha e_i^* \otimes f_\alpha$, and

$$\nabla dh = h_{ij}^\alpha e_j^* \otimes e_i^* \otimes f_\alpha + h_i^\alpha e_j^* \otimes \nabla_{e_j} e_i^* \otimes f_\alpha + h_i^\alpha e_j^* \otimes e_i^* \otimes \nabla_{e_j} f_\alpha.$$

Thus

$$0 = ddh = h_{ij}^\alpha e_j^* \wedge e_i^* \otimes f_\alpha + h_i^\alpha e_j^* \wedge \nabla_{e_j} e_i^* \otimes f_\alpha + h_i^\alpha e_j^* \wedge e_i^* \otimes \nabla_{e_j} f_\alpha.$$

However, $\nabla_{e_j} e_i^* = e_k (\nabla_{e_j} e_i^*) e_k^* = -e_i^* (\nabla_{e_j} e_k) e_k^*$ and thus

$$h_{ij}^\alpha e_j^* \wedge e_i^* \otimes f_\alpha - h_i^\alpha e_i^* (\nabla_{e_j} e_k) e_k^* \wedge e_k^* \otimes f_\alpha + h_i^\alpha h_j^\beta e_j^* \wedge e_i^* \otimes \nabla_{f_\beta} f_\gamma = 0.$$

This may be rewritten as

$$h_{ij}^\alpha e_j^* \wedge e_i^* \otimes f_\alpha - \frac{1}{2} h_i^\alpha e_i^* ([e_j, e_k]) e_j^* \wedge e_k^* \otimes f_\alpha + \frac{1}{2} h_i^\alpha h_j^\beta e_j^* \wedge e_i^* \otimes [f_\beta, f_\gamma] = 0$$

or equivalently

$$(3.9) \quad h_{ij}^\alpha e_i^* \wedge e_j^* = -\frac{1}{2} h_i^\alpha e_i^* ([e_j, e_k]) e_j^* \wedge e_k^* + \frac{1}{2} h_i^\alpha h_j^\beta f_\alpha^* ([f_\beta, f_\gamma]) e_i^* \wedge e_j^*.$$

Note that the expression h_{k0}^α for $1 \leq k \leq n_1$, $\bar{n}_1 + 1 \leq \alpha \leq \bar{n}_1 + \bar{n}_2$, occurs in the Condition 3.7. By Condition 3.3, one has $h_{0k}^\alpha = 0$, since e_k is tangent to the boundary. So, we may deduce from (3.9) that

$$(3.10) \quad h_{k0}^\alpha = \frac{1}{2} (h_k^\beta h_0^\gamma - h_0^\beta h_k^\gamma) f_\alpha^* ([f_\beta, f_\gamma]) = \sum_{\beta=1}^{\bar{n}_1} \sum_{\gamma=1}^{\bar{n}_1} h_k^\beta h_0^\gamma a_{\beta\gamma}^{\alpha-\bar{n}_1}.$$

Relabeling the indices and substituting back into Condition 3.7 gives $1 \leq \alpha \leq \bar{n}_1$,

Condition 3.11.

$$(1 + n_1 + 2n_2)h_0^\alpha(h_0^0)^2 + \sum_{j=0}^{\bar{n}_1} \sum_{\beta=1}^{\bar{n}_1} \sum_{\varepsilon=1}^{\bar{n}_1} \sum_{\mu=1}^{\bar{n}_1} \sum_{\gamma=\bar{n}_1+1}^{\bar{n}_1+\bar{n}_2} \alpha_{\beta\alpha}^{\gamma-\bar{n}_1} h_j^\beta h_j^\varepsilon \alpha_{\varepsilon\mu}^{\gamma-\bar{n}_1} h_0^\mu = 0$$

at the boundary.

In preparation for our uniqueness theorem, we deduce

Lemma 3.12. *Let $h \in C^2(M', \bar{M}')$ satisfy 3.3, 3.6, 3.7, 3.8 on M . Assume that the boundary data f satisfies $\sum_{j=n_1+1}^{n_1+n_2} \sum_{\gamma=\bar{n}_1+1}^{\bar{n}_1+\bar{n}_2} f_j^\gamma f_j^\gamma > 0$ then $h_0^0 > 0$, $h_0^\alpha = 0$ for $1 \leq \alpha \leq \bar{n}_1 + \bar{n}_2$, and $h_{k0}^\beta = h_{00}^\beta = 0$ for $\bar{n}_1 + 1 \leq \beta \leq \bar{n}_1 + \bar{n}_2$, $1 \leq k \leq n_1$.*

Proof. The inequality $h_0^0 > 0$ follows immediately from Condition 3.6 and our hypothesis about the boundary data. If $\bar{n}_1 + 1 \leq \alpha \leq \bar{n}_1 + \bar{n}_2$, then $h_0^\alpha = 0$, by Condition 3.3.

If $1 \leq \alpha \leq \bar{n}_1$, then we multiply Condition 3.11 by h_0^α and sum over α , yielding

$$(1 + n_1 + 2n_2)(h_0^0)^2 \sum_{\alpha=1}^{\bar{n}_1} (h_0^\alpha)^2 + \sum_{\gamma=\bar{n}_1+1}^{\bar{n}_1+\bar{n}_2} \sum_{j=0}^{\bar{n}_1} \left(\sum_{\varepsilon, \mu=1}^{\bar{n}_1} h_j^\varepsilon \alpha_{\varepsilon\mu}^{\gamma-\bar{n}_1} h_0^\mu \right)^2 = 0.$$

Since all terms in the sum are positive, $h_0^\alpha = 0$.

It now follows from (3.10) that $h_{k0}^\beta = 0$, for $1 \leq k \leq n_1$ and $\bar{n}_1 + 1 \leq \beta \leq \bar{n}_1 + \bar{n}_2$, since we have just shown that $h_0^\gamma = 0$, for $1 \leq \gamma \leq \bar{n}_1$. Condition 3.8 implies $h_{00}^\beta = 0$, when $\bar{n}_1 + 1 \leq \beta \leq \bar{n}_1 + \bar{n}_2$.

This allows us to derive the following uniqueness result.

Theorem 3.13. *Let h and $\hat{h}$ be proper harmonic maps between rank one symmetric spaces of noncompact type. Assume that both h and $\hat{h}$ extend to maps in $C^2(M', \bar{M}')$. If $h, \hat{h}$ both have the same boundary map $f: \partial M' \rightarrow \partial \bar{M}'$ and $\sum_{j=n_1+1}^{n_1+n_2} \sum_{\gamma=\bar{n}_1+1}^{\bar{n}_1+\bar{n}_2} f_j^\gamma f_j^\gamma > 0$ then $h = \hat{h}$, everywhere.*

Proof. Let $(y, n) \in R^+ \times N$ and $(\bar{y}, \bar{n}) \in R^+ \times \bar{N}$ be local coordinates near the boundary of M' and $\bar{M}'$. If d denotes the Riemannian distance in $\bar{M}$, then

$$d(h, \hat{h}) \leq d(h, (\bar{y}(h), \bar{n}(f))) + d((\bar{y}(h), \bar{n}(f)), (\bar{y}(\hat{h}), \bar{n}(f))) + d((\bar{y}(\hat{h}), \bar{n}(f)), \hat{h}).$$

To estimate the first term, we consider the curve $(\bar{y}(h), \bar{n}(h(t, n)))$, $0 \leq t \leq y$, which joins $(\bar{y}(h), \bar{n}(f))$ to $h = h(y, n)$. One has

$$d(h, (\bar{y}(h), \bar{n}(f))) \leq c_1 \int_0^y \left(\bar{y}^{-1} \sum_{\alpha=1}^{\bar{n}_1} |h_0^\alpha| + \bar{y}^{-2} \sum_{\alpha=\bar{n}_1+1}^{\bar{n}_1+\bar{n}_2} |h_0^\alpha| \right) dt.$$

By Lemma 3.12, $|h_0^\alpha| = O(t)$, for $1 \leq \alpha \leq \bar{n}_1 + \bar{n}_2$; $|h_0^\alpha| = o(t)$, for $\bar{n}_1 + 1 \leq \alpha \leq \bar{n}_1 + \bar{n}_2$. Since $h_0^0 > 0$, y is comparable to $\bar{y}$. So

$$d(h, (\bar{y}(h), \bar{n}(f))) \leq c_2 \left(y^{-1} \int_0^y t dt + y^{-2} \int_0^y o(t) dt \right).$$

So $d(h, (\bar{y}(h), \bar{n}(f))) = o(1)$. The third term is completely analogous.

To estimate the second term, we employ the curve $(t, \bar{n}(f))$, $\bar{y}(h) \leq t \leq \bar{y}(\hat{h})$. Condition 3.6 implies that $h_0^0 = \hat{h}_0^0$. This is because Lemma 3.12 implies $h_{j0}^\gamma = \hat{h}_{j0}^\gamma = 0$, $0 \leq j \leq n_1$, $\bar{n}_1 + 1 \leq \gamma \leq \bar{n}_1 + \bar{n}_2$, and for $1 \leq \alpha \leq \bar{n}_1$, $h_0^\alpha = \hat{h}_0^\alpha = 0$. So

$$\begin{aligned} d((\bar{y}(h), \bar{n}(f)), (\bar{y}(\hat{h}), \bar{n}(f))) &= \left| \int_{\bar{y}(h)}^{\bar{y}(\hat{h})} \frac{dt}{t} \right| = \left| \ln \left(\frac{\bar{y}(\hat{h})}{\bar{y}(h)} \right) \right| \\ &= \left| \ln \left(\frac{h_0^0 y + o(y)}{h_0^0 y + o(y)} \right) \right| = o(1). \end{aligned}$$

Thus $d^2(h, \hat{h})$ is a subharmonic function, which vanishes on $\partial M'$. It must be identically zero. The subharmonicity is well known, since the range has nonpositive curvature [10].

4. EXISTENCE

The necessary conditions of the previous section lead naturally to a construction of harmonic maps, given sufficiently regular boundary data. Assume that M and $\bar{M}$ are two rank one symmetric spaces of noncompact type, with their compactifications M' and $\bar{M}'$. Let $f: \partial M' \rightarrow \partial \bar{M}'$ be a $C^{2,\varepsilon}$ map, $0 < \varepsilon < 1$, satisfying $f_j^\gamma = 0$, $1 \leq j \leq n_1$, $\bar{n}_1 + 1 \leq \gamma \leq \bar{n}_1 + \bar{n}_2$. Our goal is to construct a harmonic map $M \rightarrow \bar{M}$, which assumes the boundary values f . This will be achieved by constructing a map h , with boundary data f , whose tension field decays to zero at infinity, and then applying the nonlinear heat equation to deform our approximate solution to a harmonic map.

Our first step is to establish a converse to the necessary conditions of §3.

Lemma 4.1. *Let $h \in C^{2,\varepsilon}(M', \bar{M}')$, $0 < \varepsilon < 1$. Such h satisfies the following conditions, at the boundary*

(i)

$$\sum_{j=0}^{n_1} \sum_{\gamma=\bar{n}_1+1}^{\bar{n}_1+\bar{n}_2} h_j^\gamma h_j^\gamma = 0,$$

(ii)

$$\begin{aligned} (n_1 + 2n_2)(h_0^0)^4 - \sum_{j=0}^{n_1} \sum_{\gamma=1}^{\bar{n}_1} h_j^\gamma h_j^\gamma (h_0^0)^2 \\ - 2 \sum_{j=0}^{n_1} \sum_{\gamma=\bar{n}_1+1}^{\bar{n}_1+\bar{n}_2} h_{j0}^\gamma h_{j0}^\gamma - 2 \sum_{j=n_1+1}^{n_1+n_2} \sum_{\gamma=\bar{n}_1+1}^{\bar{n}_1+\bar{n}_2} h_j^\gamma h_j^\gamma = 0, \end{aligned}$$

(iii)

$$(1 + n_1 + 2n_2)h_0^\alpha (h_0^0)^2 - \sum_{j=0}^{n_1} \sum_{\beta=1}^{\bar{n}_1} \sum_{\gamma=\bar{n}_1+1}^{\bar{n}_1+\bar{n}_2} a_{\alpha\beta}^{\gamma-\bar{n}_1} h_j^\beta h_{j0}^\gamma = 0, \quad 1 \leq \alpha \leq \bar{n}_1,$$

(iv)

$$h_0^0 h_{00}^\alpha = 0, \quad \bar{n}_1 + 1 \leq \alpha \leq \bar{n}_1 + \bar{n}_2,$$

whenever $\tau^0(h) = O(y^{1+\varepsilon})$; $\tau^\alpha(h) = O(y^{1+\varepsilon})$, $1 \leq \alpha \leq \bar{n}_1$; $\tau^\alpha(h) = O(y^{2+\varepsilon})$, $\bar{n}_1 + 1 \leq \alpha \leq \bar{n}_1 + \bar{n}_2$. Conversely, if conditions (i)–(iv) hold, then the components $\tau^\alpha(h)$, of the tension field, have the indicated decay as $y \downarrow 0$, provided $h_0^0 > 0$.

Proof. In §3, we established (i)–(iv), for any $h \in C^2(M', \bar{M}')$, whose tension field decays as supposed. The converse assertion follows from (2.5). If $h_0^0 > 0$, then the second order Taylor expansion, of h , gives corresponding approximations for the components of $\tau(h)$. Conditions (i) and (ii) force the vanishing of the first two terms approximating $\tau^0(h)$, the remainder is of order $y^{1+\varepsilon}$. Conditions (iii), (i) imply that the lead two terms for $\tau^\alpha(h)$, $1 \leq \alpha \leq \bar{n}_1$, are zero, so $\tau^\alpha(h) = O(y^{1+\varepsilon})$. Lastly, conditions (iv), (i) imply that the first two terms for $\tau^\alpha(h)$, $\bar{n}_1 + 1 \leq \alpha \leq \bar{n}_1 + \bar{n}_2$, are zero, so $\tau^\alpha(h) = O(y^{2+\varepsilon})$.

Next, we construct an asymptotically harmonic map, with appropriately given boundary values:

Proposition 4.2. *Suppose that $f \in C^{2,\varepsilon}(\partial M', \partial \bar{M}')$, $0 < \varepsilon < 1$, satisfies $f_j^\gamma = 0$, $1 \leq j \leq n_1$, $\bar{n}_1 + 1 \leq \gamma \leq \bar{n}_1 + \bar{n}_2$, and $\sum_{j=n_1+1}^{n_1+n_2} \sum_{\gamma=\bar{n}_1+1}^{\bar{n}_1+\bar{n}_2} f_j^\gamma f_j^\gamma > 0$. Then there exists $h \in C^{2,\varepsilon}(M', \bar{M}')$, assuming the boundary values f continuously, with $\|\tau(h)\| = O(y^\varepsilon)$. Here $\|\tau(h)\|$ is the norm of the tension field in the Riemannian norm.*

Proof. Motivated by (ii) of Lemma 4.1, we let $\phi > 0$ be a solution of

$$(n_1 + 2n_2)\phi^4 - \sum_{j=1}^{n_1} \sum_{\gamma=1}^{\bar{n}_1} f_j^\gamma f_j^\gamma \phi^2 - 2 \sum_{j=n_1+1}^{n_1+n_2} \sum_{\gamma=\bar{n}_1+1}^{\bar{n}_1+\bar{n}_2} f_j^\gamma f_j^\gamma = 0.$$

In our local chart near the boundary, we extend ϕ , by convolving with a smoothing kernel, commensurable to the Euclidean Poisson kernel. Since $f \in C^{2,\varepsilon}$, ϕ and its extension lies in $C^{1,\varepsilon}$, moreover [11], $|\nabla_0^2 \phi| = O(y^{\varepsilon-1})$, by an elementary Poisson kernel estimate. Here $|\nabla_0^2 \phi|$ is a locally defined Euclidean norm, in our chart. Define $h(y, n) = (y\phi(y, n), f(n))$. Then $h \in C^{2,\varepsilon}$.

For this h , $h_0^0 = \phi$; $h_0^\alpha = 0$, $1 \leq \alpha \leq \bar{n}_1 + \bar{n}_2$, $h_{00}^\alpha = 0$, $\bar{n}_1 + 1 \leq \alpha \leq \bar{n}_1 + \bar{n}_2$; $h_{j0}^\gamma = 0$, $1 \leq j \leq n_1$, $\bar{n}_1 + 1 \leq \gamma \leq \bar{n}_1 + \bar{n}_2$, and h restricts to f on $\partial M'$. Thus, conditions (i)–(iv) of Lemma 4.1 hold at the boundary. By Lemma 4.1 and the expression (2.2) of the metric $\|\tau(h)\| = O(y^\varepsilon)$. This completes the local construction. Since $\|\tau(h)\| = O(y^\varepsilon)$, and Lemma 4.1 is an equivalence statement, (i)–(iv) are valid in any coordinate patch. Thus, the conclusion of Lemma 3.12 holds, not just in the chart where h was constructed, but in any overlapping chart. We now fit together our local solutions via partition of unity, along the boundary. The partition functions can be chosen independent of y , near $\partial \bar{M}'$. The conclusion of Lemma 3.12 is seen to hold for our global solution. However, this implies (i)–(iv) of Lemma 4.1 and thus $\|\tau(h)\| = O(y^\varepsilon)$.

The deformation, via the nonlinear heat equation, employs certain superharmonic functions as barriers. In standard notation, let r denote the geodesic distance from the basepoint in our rank one symmetric space M . One has

Lemma 4.3. *Assume that r_0 is sufficiently large. Define, for any given $0 < s \leq n_1 + 2n_2$, $\psi(r) = e^{-sr}$, $r \geq r_0$, and $\psi(r) = e^{-sr_0}$, $r \leq r_0$. Then ψ is superharmonic, on M .*

Proof. In exponential polar coordinates (r, w) , the volume element is written as $(\sinh r)^{n_1}(\sinh 2r)^{n_2} dr dw$. To check our normalization of metric, observe that r is commensurable to $-\ln y$ in (2.2). If $r \geq r_0$, the standard expression for the Laplacian of a radial function gives

$$\begin{aligned}\Delta\psi(r) &= \psi''(r) + \left(n_1 \frac{\cosh r}{\sinh r} + 2n_2 \frac{\cosh 2r}{\sinh 2r}\right) \psi'(r) \\ &= s \left(s - n_1 \frac{\cosh r}{\sinh r} - 2n_2 \frac{\cosh 2r}{\sinh 2r}\right) \psi(r).\end{aligned}$$

So $\Delta\psi(r) \leq 0$, because $0 < s \leq n_1 + 2n_2$. Since the minimum of two superharmonic functions is superharmonic and superharmonic is a local concept, ψ is superharmonic on all of M .

Combining Proposition 4.2, Lemma 4.3, and the method of Li and Tam [8], one deduces

Theorem 4.4. *Suppose that $f \in C^{2,\varepsilon}(\partial M', \partial \overline{M}')$, $0 < \varepsilon < 1$, satisfies $f_j^\gamma = 0$, $1 \leq j \leq n_1$, $\bar{n}_1 + 1 \leq \gamma \leq \bar{n}_1 + \bar{n}_2$, and $\sum_{j=n_1+1}^{n_1+n_2} \sum_{\gamma=\bar{n}_1+1}^{\bar{n}_1+\bar{n}_2} f_j^\gamma f_j^\gamma > 0$. Then there exists a harmonic map $u: M \rightarrow \overline{M}$, which assumes the boundary values f , continuously. If h is the map of Proposition 4.2, then the Riemannian distance from h to u is $O(y^{\bar{\varepsilon}})$, in any standard local chart near the boundary, for any $\bar{\varepsilon} < \varepsilon$.*

Proof. Suppose that u_t is the solution to the nonlinear heat equation with initial data h . Since $\|\tau(h)\|^2$ lies in some L^p , $p > 1$, $\tau(h)$ is bounded, and h has bounded energy density, it follows [7] that u_t exists and converges to a harmonic map $u = u_\infty$, as $t \rightarrow \infty$. Hartman [5] showed that $\|u_t\|$ is a subsolution to the usual linear heat equation. Choosing $s = \varepsilon$, in Lemma 4.3, we get an infinite number of subsolutions $\|u_t\| - c\psi$, any $c \geq 0$. If c is large enough, then, at $t = 0$, $\|u_t\| - c\psi = \|\tau(h)\| - c\psi < 0$, by the decay estimate for $\tau(h)$ in Proposition 4.2. The maximum principle gives $\|\tau(u_t)\| < c\psi$, for all t . The general existence theorem of [7] states that $\|\tau(u_t)\| < c_1 e^{-c_2 t}$, for some positive constants c_1 and c_2 .

Thus, for any T ,

$$d(h, u) \leq \int_0^\infty \|u_t\| dt = \int_0^T \|u_t\| dt + \int_0^\infty \|u_t\| dt.$$

The conclusion follows by choosing T of order $-\log \psi$, for points near the ideal boundary at infinity, $\partial M'$.

Suppose that the image $\overline{M}$ is a hyperbolic space of constant negative curvature -1 . In this case, the regularity requirement of Theorem 4.4 may be significantly lowered. The analogue of Lemma 4.1 is

Lemma 4.5. *Suppose $h \in C^{1,\varepsilon}(M', \overline{M}') \cap C^2(M, \overline{M})$, $0 < \varepsilon < 1$, with $\overline{M}$ of constant negative curvature -1 . Such h satisfies the following conditions, at the boundary:*

- (i) $(n_1 + 2n_2)(h_0^0)^2 - \sum_{j=0}^{n_1} \sum_{\gamma=1}^{\bar{n}_1} h_j^\gamma h_j^\gamma = 0$,
- (ii) $h_0^0 h_0^\alpha = 0$, $\alpha \geq 1$,

whenever $\tau^\alpha(h) = O(y^{1+\varepsilon})$, $\alpha \geq 0$. Conversely, suppose that for the Euclidean norm, in any local coordinate chart, $|\nabla^2 h| = O(y^{\varepsilon-1})$. If $h_0^0 > 0$ and conditions (i), (ii) both hold, then $\tau^\alpha(h) = O(y^{1+\varepsilon})$, $\alpha \geq 0$.

Proof. If $\tau^\alpha(h) = O(y^{1+\varepsilon})$, then we proved (i), (ii) in §3, for $h \in C^1(M', \overline{M}') \cap C^2(M, \overline{M})$. Conversely, the hypothesis $|\nabla^2 h| = O(y^{\varepsilon-1})$, shows that the second derivative terms in (2.5a) are of order $y^{1+\varepsilon}$. If $h_0^0 > 0$, then (i) gives the vanishing of the first derivative terms, in formula (2.5a) for $\tau^0(h)$, up to order $y^{1+\varepsilon}$. Similarly, (ii) handles the first derivative terms for $\tau^\alpha(h)$, $\alpha \geq 1$.

Following our earlier scheme, we construct an asymptotically harmonic map, given appropriate boundary data.

Proposition 4.6. Assume that $f \in C^{1,\varepsilon}(\partial M', \partial \overline{M})$, $0 < \varepsilon < 1$, satisfies

$$\sum_{j=1}^{n_1} \sum_{\gamma=1}^{\bar{n}_1} f_j^\gamma f_j^\gamma > 0.$$

Then there exists $h \in C^{1,\varepsilon}(M', \overline{M}') \cap C^2(M, \overline{M})$, assuming the boundary values f continuously, with $\|\tau(h)\| = O(y^\varepsilon)$, the Riemannian norm, of our space $\overline{M}$ with constant negative curvature.

Proof. Denote

$$\phi = \left[\sum_{j=1}^{n_1} \sum_{\gamma=1}^{\bar{n}_1} \frac{f_j^\gamma f_j^\gamma}{n_1 + 2n_2} \right]^{1/2},$$

as suggested by the hypothesis (i) of Lemma 4.5. Clearly, $\phi \in C^{0,\varepsilon}(\partial M')$, and we extend ϕ locally by convolving with the smoothing kernel, comparable to the Poisson kernel. In contrast to the proof of Proposition 4.2, we only have $f \in C^{1,\varepsilon}$. So we must also extend f , by convolution with a kernel comparable to the Poisson kernel, using the components of f in some chart near $\partial \overline{M}'$. We now define

$$h(y, n) = \left(y\phi(y, n), f(y, n) - \frac{\partial f}{\partial y}(0, n)y \right).$$

Elementary estimates for Poisson smoothing [11], now show that $h \in C^{1,\varepsilon}(M', \overline{M}')$, as in the proof of Proposition 4.2. Moreover, $h_0^0 = \phi$ and $h_0^\alpha = 0$, $\alpha \geq 1$, at the boundary $\partial M'$. Since h has boundary values f , $h(0, n) = (0, f(0, n))$, conditions (i), (ii) of Lemma 4.5 are valid. The Poisson smoothing guarantees that $|\nabla^2 h| = O(y^{\varepsilon-1})$. Thus, Lemma 4.5 yields $\|\tau(h)\| = O(y^\varepsilon)$. Since $\overline{M}$ has constant negative curvature, the norm is y^{-1} times the locally defined Euclidean norm. This completes the local construction, on a chart near $\partial M'$. One patches these local solutions together using a partition of unity along $\partial M'$. The partition functions can be chosen independent of y , near $\partial M'$, so that $h_0^0 = \phi$ and $h_0^\alpha = 0$, $\alpha \geq 1$, for the globally defined h , in any local chart. Lemma 4.5 again gives $\|\tau^\alpha(h)\| = O(y^\varepsilon)$.

We now invoke Lemma 4.3 and apply the same argument as in the proof of Theorem 4.4, to deduce

Theorem 4.7. Assume that $\overline{M}$ is the simply connected complete space having constant negative curvature -1 . Let M be a rank one symmetric space of noncompact type.

Suppose that $f \in C^{1,\varepsilon}(\partial M', \partial \overline{M}')$, $0 < \varepsilon < 1$, satisfies $\sum_{j=1}^{n_1} \sum_{\gamma=1}^{\overline{n}_1} f_j^\gamma f_j^\gamma > 0$. Then there exists a harmonic map $u: M \rightarrow \overline{M}$, which assumes the boundary values f , continuously. If h is the map of Proposition 4.6, then the Riemannian distance from h to u is $O(y^{\bar{\varepsilon}})$, for any $\bar{\varepsilon} < \varepsilon$.

Remark. By applying the arguments of [9], it suffices to assume $f \in C^2(\partial M', \partial \overline{M}')$ in the hypothesis of Theorem 4.4. Similarly, one may suppose $f \in C^1(\partial M', \partial \overline{M}')$ in Theorem 4.7. We omit the details since these refinements are not needed in the subsequent sections of this paper. A more careful discussion will be given elsewhere.

5. HIGHER ORDER APPROXIMATE SOLUTIONS AND COMPATIBILITY CONDITIONS

Let M and $\overline{M}$ be rank one Riemannian symmetric spaces of noncompact type. Suppose that $f \in C^{2,\varepsilon}(\partial M', \partial \overline{M}')$ satisfies the hypothesis of Proposition 4.2. We showed that there exists $h \in C^{2,\varepsilon}(M', \overline{M}')$, assuming the boundary values f continuously, whose tension field satisfies $\|\tau(h)\| = O(y^\varepsilon)$. If the boundary data is smoother, $f \in C^{l+2,\varepsilon}(\partial M', \partial \overline{M}')$, then we will modify h to achieve $\|\tau(h)\| = O(y^{l+\varepsilon})$. It is already clear, from the proof of Proposition 4.2, that the h constructed there lies in $C^{l+2,\varepsilon}(M', \overline{M}')$, whenever $f \in C^{l+2,\varepsilon}(\partial M', \partial \overline{M}')$. The point is to improve the decay rate of the tension field. One proceeds by an inductive argument, which is valid as long as $l \leq n_1 + 2n_2$. The breakdown after a finite number of steps is expected by analogy with the studies of related problems in [4] and [8]. These higher order approximate solutions, besides being of intrinsic interest, play an important role in our subsequent development of regularity theory.

To set up the induction, assume that $h \in C^{l+2,\varepsilon}$, $l \geq 1$, $0 < \varepsilon < 1$, has boundary values $f \in C^{l+2,\varepsilon}$. Suppose that $h_0^\alpha > 0$; $h_0^\alpha = 0$, $1 \leq \alpha \leq \overline{n}_1 + \overline{n}_2$, $h_{00}^\alpha = 0$, $\overline{n}_1 + 1 \leq \alpha \leq \overline{n}_1 + \overline{n}_2$; $h_{j0}^\gamma = 0$, $1 \leq j \leq n_1$, $\overline{n}_1 + 1 \leq \gamma \leq \overline{n}_1 + \overline{n}_2$. If $k < l + 2$, assume that $\partial^{i-1} h_0^\alpha / \partial y^{i-1}$ are determined for $i < k$ and all α . Moreover, suppose that $\partial^{i-1} h_0^\alpha / \partial y^{i-1}$ are determined for $i \leq k$, $\alpha \geq \overline{n}_1 + 1$. These modifications have been made to achieve $|\tau^\alpha(h)| = O(y^k)$, all α ; and $|\tau^\alpha(h)| = O(y^{k+1})$, $\alpha \geq \overline{n}_1 + 1$. To start the induction, with $k = 2$, we use the proofs of Propositions 4.2, 4.6. Let Q_k denote a rational function of the already determined data. Note that if $\partial^{i-1} h_0^\alpha / \partial y^{i-1}$ is determined, then so are its tangential derivatives, as long as the total number of derivatives is at most $l + 2$.

The inductive argument requires some detailed calculations, starting from the formulas (2.5). It is convenient to divide the presentation into three cases, depending upon the index α in $\tau^\alpha(h)$.

Case 1. $\alpha \geq \overline{n}_1 + 1$. By formula (2.5),

$$\tau^\alpha(h) = g^{jj} h_{jj}^\alpha + (1 - n_1 - 2n_2) h_0^\alpha y - 4g^{jj} h_j^0 h_j^\alpha y^{-1}$$

where $0 \leq j \leq n_1 + n_2$ is summed. Thus, by the decomposition (2.2) of the

metric,

$$\begin{aligned}\tau^\alpha(h) &= y^2 h_{00}^\alpha + \sum_{j=1}^{n_1} y^2 h_{jj}^\alpha + \sum_{j=n_1+1}^{n_1+n_2} y^4 h_{jj}^\alpha + (1 - n_1 - 2n_2) h_0^\alpha y \\ &\quad - 4 \left(\frac{y^2}{\bar{y}} \right) h_0^0 h_0^\alpha - 4 \left(\frac{y^2}{\bar{y}} \right) \sum_{j=1}^{n_1} h_j^0 h_j^\alpha - 4 \left(\frac{y^4}{\bar{y}} \right) \sum_{j=n_1+1}^{n_1+n_2} h_j^0 h_j^\alpha.\end{aligned}$$

We now separate out those terms Q_k already fixed at an earlier step of the induction

$$\tau^\alpha(h) = y^2 h_{00}^\alpha + (1 - n_1 - 2n_2) h_0^\alpha y - 4(y^2/\bar{y}) h_0^0 h_0^\alpha + Q_k y^{k+1} + O(y^{k+1+\varepsilon}).$$

Here, we used the fact that $h_j^0 = 0$, $j \geq 1$; $h_0^\alpha = 0$, $\alpha \geq 1$, along the boundary. Using Taylor expansion of the remaining terms, we deduce, since $h_{00}^\alpha = 0$ at the boundary,

$$k! \tau^\alpha(h) = (k - n_1 - 2n_2 - 3) \frac{\partial^k h_0^\alpha}{\partial y^k} y^{k+1} + Q_k y^{k+1} + O(y^{k+1+\varepsilon}).$$

If $k+1 < l+2$, the remainder term is $O(y^{k+2})$. Since $l \leq n_1 + 2n_2$ and $k < l+2$, we may solve uniquely for $\partial^k h_0^\alpha / \partial y^k$, in terms of Q_k , to assure that $\tau^\alpha(h) = O(y^{k+1+\varepsilon})$ and $\tau^\alpha(h) = O(y^{k+2})$, as long as $k+1 < l+2$.

Case 2. $1 \leq \alpha \leq \bar{n}_1$. Again, starting from (2.5),

$$\begin{aligned}\tau^\alpha(h) &= g^{jj} h_{jj}^\alpha + (1 - n_1 - 2n_2) h_0^\alpha y - 2g^{jj} h_j^0 h_j^\alpha \bar{y}^{-1} \\ &\quad + g^{jj} \sum_{\beta=1}^{\bar{n}_1} \sum_{\gamma=\bar{n}_1+1}^{\bar{n}_1+\bar{n}_2} a_{\alpha\beta}^{\gamma-\bar{n}_1} h_j^\beta h_j^\gamma \bar{y}^{-2}\end{aligned}$$

with j summed from 0 to $n_1 + n_2$. Using the local expression (2.2) for the metric,

$$\begin{aligned}\tau^\alpha(h) &= y^2 h_{00}^\alpha + y^2 \sum_{j=1}^{n_1} h_{jj}^\alpha + y^4 \sum_{j=n_1+1}^{n_1+n_2} h_{jj}^\alpha + (1 - n_1 - 2n_2) h_0^\alpha y \\ &\quad - 2y^2 h_0^0 h_0^\alpha \bar{y}^{-1} - 2y^2 \bar{y}^{-1} \sum_{j=1}^{n_1} h_j^0 h_j^\alpha - 2y^4 \bar{y}^{-1} \sum_{j=n_1+1}^{n_1+n_2} h_j^0 h_j^\alpha \\ &\quad + y^2 \bar{y}^{-2} \sum_{\beta=1}^{\bar{n}_1} \sum_{\gamma=\bar{n}_1+1}^{\bar{n}_1+\bar{n}_2} a_{\alpha\beta}^{\gamma-\bar{n}_1} h_0^\beta h_0^\gamma \\ &\quad + y^2 \bar{y}^{-2} \sum_{j=1}^{n_1} \sum_{\beta=1}^{\bar{n}_1} \sum_{\gamma=\bar{n}_1+1}^{\bar{n}_1+\bar{n}_2} a_{\alpha\beta}^{\gamma-\bar{n}_1} h_j^\beta h_j^\gamma \\ &\quad + y^4 \bar{y}^{-2} \sum_{j=n_1+1}^{n_1+n_2} \sum_{\beta=1}^{\bar{n}_1} \sum_{\gamma=\bar{n}_1+1}^{\bar{n}_1+\bar{n}_2} a_{\alpha\beta}^{\gamma-\bar{n}_1} h_j^\beta h_j^\gamma.\end{aligned}$$

Identifying certain terms Q_k already fixed at an earlier inductive step:

$$\tau^\alpha(h) = y^2 h_{00}^\alpha + (1 - n_1 - 2n_2) h_0^\alpha y - 2(y^2/\bar{y}) h_0^0 h_0^\alpha + Q_k y^k + O(y^{k+\varepsilon}).$$

The hypotheses $h_0^\alpha = 0$, $\alpha \geq 1$; $h_{00}^\gamma = 0$, $\gamma \geq \bar{n}_1 + 1$; $h_{j0}^\gamma = 0$, $\gamma \geq \bar{n}_1 + 1$, $1 \leq j \leq n_1$, were needed here, at the boundary. Taylor expanding the relevant terms gives

$$(k-1)!\tau^\alpha(h) = (k-n_1-2n_2-2)\frac{\partial^{k-1}h_0^\alpha}{\partial y^{k-1}}y^k + Q_k y^k + O(y^{k+\varepsilon}).$$

If $k+1 < l+2$, then the remainder is of order $O(y^{k+1})$. Since $k < l+2$ and $l \leq n_1 + 2n_2$, the derivative $\partial^{k-1}h_0^\alpha/\partial y^{k-1}$ is uniquely determined, in terms of the previously known data Q_k , to give $\tau^\alpha(h) = O(y^{k+\varepsilon})$ and in fact the better condition $\tau^\alpha(h) = O(y^{k+1})$, as long as $k+1 < l+2$.

Case 3. $\alpha = 0$. Returning to (2.5), we have

$$\begin{aligned} \tau^0(h) &= g^{jj}h_{jj}^0 + (1-n_1-2n_2)h_0^0y - g^{jj}h_j^0h_j^0\bar{y}^{-1} \\ &\quad + g^{jj}\sum_{\gamma=1}^{\bar{n}_1}h_j^\gamma h_j^\gamma\bar{y}^{-1} + g^{jj}\sum_{\gamma=\bar{n}_1+1}^{\bar{n}_1+\bar{n}_2}h_j^\gamma h_j^\gamma(2\bar{y}^{-3}) \end{aligned}$$

where one sums j from 0 to $n_1 + n_2$. Breaking this into pieces corresponding to the splitting (2.2) of the metric, we have

$$\begin{aligned} \tau^0(y) &= y^2h_{00}^0 + \sum_{j=1}^{n_1}y^2h_{jj}^0 + \sum_{j=n_1+1}^{n_1+n_2}y^4h_{jj}^0 + (1-n_1-2n_2)h_0^0y \\ &\quad - y^2(h_0^0)^2\bar{y}^{-1} - y^2\sum_{j=1}^{n_1}h_j^0h_j^0\bar{y}^{-1} - y^4\sum_{j=n_1+1}^{n_1+n_2}h_j^0h_j^0\bar{y}^{-1} \\ &\quad + y^2\sum_{\gamma=1}^{\bar{n}_1}(h_0^\gamma)^2\bar{y}^{-1} + y^2\sum_{j=1}^{n_1}\sum_{\gamma=1}^{\bar{n}_1}h_j^\gamma h_j^\gamma\bar{y}^{-1} \\ &\quad + y^4\sum_{j=n_1+1}^{n_1+n_2}\sum_{\gamma=1}^{\bar{n}_1}h_j^\gamma h_j^\gamma\bar{y}^{-1} + 2\sum_{\gamma=\bar{n}_1+1}^{\bar{n}_1+\bar{n}_2}h_0^\gamma h_0^\gamma y^2\bar{y}^{-3} \\ &\quad + 2y^2\sum_{j=1}^{n_1}\sum_{\gamma=\bar{n}_1+1}^{\bar{n}_1+\bar{n}_2}h_j^\gamma h_j^\gamma\bar{y}^{-3} + 2y^4\sum_{j=n_1+1}^{n_1+n_2}\sum_{\gamma=\bar{n}_1+1}^{\bar{n}_1+\bar{n}_2}h_j^\gamma h_j^\gamma\bar{y}^{-3}. \end{aligned}$$

Isolating appropriate terms Q_k which are previously determined,

$$\begin{aligned} \tau^0(h) &= y^2h_{00}^0 + (1-n_1-2n_2)h_0^0y - y^2(h_0^0)^2\bar{y}^{-1} \\ &\quad + y^2\bar{y}^{-1}\sum_{j=1}^{n_1}\sum_{\gamma=1}^{\bar{n}_1}h_j^\gamma h_j^\gamma + 2y^4\bar{y}^{-3}\sum_{j=n_1+1}^{n_1+n_2}\sum_{\gamma=\bar{n}_1+1}^{\bar{n}_1+\bar{n}_2}h_j^\gamma h_j^\gamma + Q_k y^k + O(y^{k+\varepsilon}). \end{aligned}$$

Again, we used the facts $h_0^\alpha = 0$, $\alpha \geq 1$; $h_{00}^\gamma = 0$, $h_{j0}^\gamma = 0$, $\gamma \geq \bar{n}_1 + 1$, $1 \leq j \leq n_1$.

Using Taylor polynomials to estimate each remaining term gives

$$k!\tau^0(h) = \left[1 + k(k - n_1 - 2n_2 - 2) - \left(\frac{1}{h_0^0} \right)^2 \sum_{j=1}^{n_1} \sum_{\gamma=1}^{\bar{n}_1} h_j^\gamma h_j^\gamma \right. \\ \left. - \frac{6}{(h_0^0)^4} \sum_{j=n_1+1}^{n_1+n_2} \sum_{\gamma=\bar{n}_1+1}^{\bar{n}_1+\bar{n}_2} h_j^\gamma h_j^\gamma \right] \frac{\partial^{k-1} h_0^0}{\partial y^{k-1}} y^k \\ + Q_k y^k + O(y^{k+\varepsilon}).$$

If $k+1 < l+2$, the remainder is $O(y^{k+1})$. Since $l \leq n_1 + 2n_2$ and $k < l+2$, there is a unique choice for $\partial^{k-1} h_0^0 / \partial y^{k-1}$, which forces $\tau^0(h) = O(y^{k+\varepsilon})$, in terms of previously determined data Q_k . We have $\tau^0(h) = O(y^{k+1})$, if $k+1 < l+2$.

These computations form the main part of the proof of

Proposition 5.1. *Suppose that $f \in C^{l+2,\varepsilon}(\partial M', \partial \bar{M}')$, $0 \leq l \leq n_1 + 2n_2$, $0 < \varepsilon < 1$ satisfies $f_j^\gamma = 0$, $1 \leq j \leq n_1$, $\bar{n}_1 + 1 \leq \gamma \leq \bar{n}_1 + \bar{n}_2$, and*

$$\sum_{j=n_1+1}^{n_1+n_2} \sum_{\gamma=\bar{n}_1+1}^{\bar{n}_1+\bar{n}_2} f_j^\gamma f_j^\gamma > 0.$$

Then there exists $h \in C^{l+2,\varepsilon}(M', \bar{M}')$, assuming the boundary values f , with $\|\tau(h)\| = O(y^{l+\varepsilon})$. Moreover, the covariant derivatives of the tension satisfy $\|\nabla^j \tau(h)\| = O(y^{l+\varepsilon})$, for $j \leq l$.

Proof. If $l = 0$, this reduces to Proposition 4.2. The inductive scheme just given, for $2 \leq k \leq l+1$, $l \geq 1$, applies in local charts near $\partial M'$ to give $|\tau^\alpha(h)| = O(y^{l+2+\varepsilon})$, $\alpha \geq \bar{n}_1 + 1$; $|\tau^\alpha(h)| = O(y^{l+1+\varepsilon})$, $\alpha \geq 0$. Since the metric is given by (2.2), this means that $\|\tau(h)\| = O(y^{l+\varepsilon})$, in each chart near the boundary. However, a global solution was given in Proposition 4.2, when $l = 0$. At each stage of the inductive argument, in Cases 1, 2, 3, one uniquely determines the Taylor series modification of h . This uniqueness guarantees that the local solutions agree, to sufficiently high order in y , fitting together to give a global solution. The estimates for $\nabla^j \tau(h)$ follow from successive covariant differentiation, of the Taylor polynomial of $\tau(h)$ in y , using the orthonormal frame field $y\partial/\partial y$, yX_i , y^2Z_j . Since the coefficients, on the right-hand side of (2.4), are bounded, independent of y ; and $h_j^\gamma = 0$, $0 \leq j \leq n_1$, $\bar{n}_1 + 1 \leq \gamma \leq \bar{n}_1 + \bar{n}_2$, at the boundary, $\|\nabla^j \tau(h)\|_{0,\varepsilon} = O(y^{l+\varepsilon})$, $j \leq l$.

We may now apply the nonlinear heat equation to deform our higher order approximate solution to a harmonic map. The proof of Theorem 4.4 extends easily to give

Theorem 5.2. *Suppose that $f \in C^{l+2,\varepsilon}(\partial M', \partial \bar{M}')$, $0 \leq l < n_1 + 2n_2$, $0 < \varepsilon < 1$ satisfies $f_j^\gamma = 0$, $1 \leq j \leq n_1$, $\bar{n}_1 + 1 \leq \gamma \leq \bar{n}_1 + \bar{n}_2$, and $\sum_{j=n_1+1}^{n_1+n_2} \sum_{\gamma=\bar{n}_1+1}^{\bar{n}_1+\bar{n}_2} f_j^\gamma f_j^\gamma > 0$. Then there exists a harmonic map u , which assumes the boundary values f continuously, so that $d(u, h) = O(y^{l+\bar{\varepsilon}})$, any $\bar{\varepsilon} < \varepsilon$, where h is the map of Proposition 5.1.*

Proof. One follows the proof of Theorem 4.4, almost verbatim, using Proposition 5.1 rather than Proposition 4.2. The case $l = n_1 + 2n_2$ is excluded since

then $s = l + \varepsilon > n_1 + 2n_2$, the superharmonic function ψ , of Lemma 4.3, only is available when $s \leq n_1 + 2n_2$.

Suppose now that the range $\overline{M}$ is a hyperbolic space of constant curvature -1 . The above construction of higher order approximation can then be modified to yield more attractive results. If the boundary data $f \in C^{1,\varepsilon}(\partial M', \partial \overline{M}')$, $0 < \varepsilon < 1$, satisfies the hypothesis of Proposition 4.6, then we showed that there exists an extension $h \in C^{1,\varepsilon}(M', \overline{M}') \cap C^2(M, \overline{M})$, with $\|\tau(h)\| = O(y^\varepsilon)$. For smoother boundary values $f \in C^{l+1,\varepsilon}(\partial M', \partial \overline{M}')$, we plan to modify h to achieve $\|\tau(h)\| = O(y^{l+\varepsilon})$, as long as $l \leq n_1 + 2n_2$. It is already clear, from the proof of Proposition 4.6, that the h constructed there lies in $C^{l+1,\varepsilon}(M', \overline{M}')$, whenever $f \in C^{l+1,\varepsilon}(M', \overline{M}')$. The point is to improve the decay rate of the tension field.

To set up the induction, assume that $h \in C^{l+1,\varepsilon}$, $l \geq 1$, $0 < \varepsilon < 1$, has continuously assumed boundary values $f \in C^{l+1,\varepsilon}$. Assume that $h_0^0 > 0$; $h_0^\alpha = 0$, $1 \leq \alpha \leq n_1 + n_2$; $|\nabla_0^{l+2} h| = O(y^{\varepsilon-1})$, where ∇_0 denotes Euclidean derivatives in any local chart. If $k < l + 1$, assume that $\partial^{i-1} h_0^\alpha / \partial y^{i-1}$ are determined for $i \leq k$, $\alpha \geq 0$. These modifications have been made to achieve $|\tau^\alpha(h)| = O(y^{k+1})$, all α . To start the induction, with $k = 1$, we invoke the proof of Proposition 4.6. Let Q_k denote a rational function of the already determine data.

Again, we use formulas (2.5a) and divide the discussion into the cases, depending upon the index α in $\tau^\alpha(h)$:

Case 1. $\alpha \geq 1$. Quoting from (2.5a) gives

$$\tau^\alpha(h) = g^{jj} h_{jj}^\alpha + (1 - n_1 - 2n_2) h_0^\alpha y - 2g^{jj} h_j^0 h_j^\alpha \bar{y}^{-1}$$

with j summed from 0 to $n_1 + n_2$. Separating this into pieces corresponding to the splitting (2.2) of the metric, gives

$$\begin{aligned} \tau^\alpha(h) = & y^2 h_{00}^\alpha + y^2 \sum_{j=1}^{n_1} h_{jj}^\alpha + y^4 \sum_{j=n_1+1}^{n_1+n_2} h_{jj}^\alpha + (1 - n_1 - 2n_2) h_0^\alpha y \\ & - 2y^2 h_0^0 h_0^\alpha \bar{y}^{-1} - 2y^2 \sum_{j=1}^{n_1} h_j^0 h_j^\alpha \bar{y}^{-1} - 2y^4 \sum_{j=n_1+1}^{n_1+n_2} h_j^0 h_j^\alpha \bar{y}^{-1}. \end{aligned}$$

We now identify the terms Q_k already fixed:

$$\tau^\alpha(h) = y^2 h_{00}^\alpha + (1 - n_1 - 2n_2) h_0^\alpha y - 2y^2 h_0^0 h_0^\alpha \bar{y}^{-1} + Q_k y^{k+1} + O(y^{k+1+\varepsilon}).$$

Here, we used the fact that $h_j^0 = 0$, at the boundary, $j \geq 1$. Using the Taylor polynomial of the significant terms:

$$k! \tau^\alpha(h) = (k - n_1 - 2n_2 - 1) \frac{\partial^k h_0^\alpha}{\partial y^k} y^{k+1} + Q_k y^{k+1} + O(y^{k+1+\varepsilon}).$$

If $k + 1 < l + 1$, then the remainder is of order $O(y^{k+2})$. Since $k < l + 1$ and $l \leq n_1 + 2n_2$, the derivative $\partial^k h_0^\alpha / \partial y^k$ is uniquely determined, in terms of the previously known data Q_k , to give $\tau^\alpha(h) = O(y^{k+1+\varepsilon})$, and in fact the better condition $\tau^\alpha(h) = O(y^{k+2})$, as long as $k + 1 < l + 1$.

Case 2. $\alpha = 0$. Using (2.5a) again,

$$\tau^0(h) = g^{jj}h_{jj}^0 + (1 - n_1 - 2n_2)h_0^0y - g^{jj}h_j^0h_j^0\bar{y}^{-1} + g^{jj}\sum_{\gamma=1}^{\bar{n}_1}h_j^\gamma h_j^\gamma \bar{y}^{-1}$$

where $0 \leq j \leq n_1 + n_2$ is summed. Separating into pieces corresponding to the splitting (2.2) of the metric yields

$$\begin{aligned}\tau^0(h) &= y^2h_{00}^0 + \sum_{j=1}^{n_1}y^2h_{jj}^0 + \sum_{j=n_1+1}^{n_1+n_2}y^4h_{jj}^0 + (1 - n_1 - 2n_2)h_0^0y \\ &\quad - y^2(h_0^0)^2\bar{y}^{-1} - y^2\sum_{j=1}^{n_1}h_j^0h_j^0\bar{y}^{-1} - y^4\sum_{j=n_1+1}^{n_1+n_2}h_j^0h_j^0\bar{y}^{-1} \\ &\quad + y^2\sum_{\gamma=1}^{\bar{n}_1}h_0^\gamma h_0^\gamma \bar{y}^{-1} + \sum_{j=1}^{n_1}\sum_{\gamma=1}^{\bar{n}_1}y^2h_j^\gamma h_j^\gamma \bar{y}^{-1} \\ &\quad + y^4\sum_{j=n_1+1}^{n_1+n_2}\sum_{\gamma=1}^{\bar{n}_1}h_j^\gamma h_j^\gamma \bar{y}^{-1}.\end{aligned}$$

Identifying terms of type Q_k , which are already determined:

$$\begin{aligned}\tau^0(h) &= y^2h_{00}^0 + (1 - n_1 - 2n_2)h_0^0y - y^2(h_0^0)^2\bar{y}^{-1} \\ &\quad + y^2\bar{y}^{-1}\sum_{j=1}^{n_1}\sum_{\gamma=1}^{\bar{n}_1}h_j^\gamma h_j^\gamma + Q_k y^{k+1} + O(y^{k+1+\varepsilon}).\end{aligned}$$

Here, we used the hypotheses that $h_j^0 = 0$, $j \geq 1$, and $h_0^\alpha = 0$, $\alpha \geq 1$, along the boundary.

Expanding the relevant terms in Taylor series yields

$$\begin{aligned}(k+1)!\tau^0(h) &= \left[1 + (k+1)(k - n_1 - 2n_2 - 1) - \left(\frac{1}{h_0^0}\right)^2 \sum_{j=1}^{n_1}\sum_{\gamma=1}^{\bar{n}_1}h_j^\gamma h_j^\gamma \right] \frac{\partial^k h_0^0}{\partial y^k} y^{k+1} \\ &\quad + Q_k y^{k+1} + O(y^{k+\varepsilon+1}).\end{aligned}$$

If $k+1 < l+1$, the remainder is $O(y^{k+2})$. Since $k < l+1$ and $l \leq n_1 + 2n_2$, the derivative $\partial^k h_0^0 / \partial y^k$ is uniquely determined, in terms of already known data Q_k , to give $\tau^0(h) = O(y^{k+1+\varepsilon})$, and actually $\tau^0(h) = O(y^{k+2})$, when $k+1 < l+1$.

Arguing as in the proof of Proposition 5.1, we employ these calculations to deduce an extension of Proposition 4.6.

Proposition 5.3. Assume that $f \in C^{l+1,\varepsilon}(\partial M', \partial \bar{M}')$, $0 < \varepsilon < 1$, satisfies $\sum_{j=1}^{n_1} \sum_{\gamma=1}^{\bar{n}_1} f_j^\gamma f_j^\gamma > 0$. Then there exists $h \in C^{l+1,\varepsilon}(M', \bar{M}') \cap C^2(M, \bar{M})$, $l \geq 0$, assuming the boundary values f continuously, with $\|\tau(h)\| = O(y^{l+\varepsilon})$, as long as $l \leq n_1 + 2n_2$. Moreover, the covariant derivatives of the tension satisfy $\|\nabla^j \tau(h)\|_{0,\varepsilon} = O(y^{l+\varepsilon})$, for $j \leq l$.

Applying the nonlinear heat equation, with initial data h , gives the analogue of Theorem 5.2.

Theorem 5.4. *Suppose that $\bar{M}$ is a hyperbolic space of constant negative curvature -1 . Assume that $f \in C^{l+1,\varepsilon}(\partial M', \partial \bar{M}')$, $0 < \varepsilon < 1$, $0 \leq l < n_1 + 2n_2$, satisfies $\sum_{j=1}^{n_1} \sum_{\gamma=1}^{\bar{n}_1} f_j^\gamma f_j^\gamma > 0$. Then there exists a harmonic map u , assuming the boundary values f continuously, so that $d(u, h) = O(y^{l+\bar{\varepsilon}})$, and $\bar{\varepsilon} < \varepsilon$, where h is the map of Proposition 5.3.*

6. BOUNDARY REGULARITY

Assume that M and $\bar{M}$ are globally symmetric spaces of noncompact type and rank one. Given $f \in C^{l+2,\varepsilon}(\partial M', \partial \bar{M}')$, satisfying the hypotheses of Proposition 5.1, we extended f to an asymptotically harmonic map $h \in C^{l+2,\varepsilon}(M', \bar{M}')$, with $\|\nabla^j \tau(h)\|_{0,\varepsilon} = O(y^{l+\varepsilon})$, $j \leq l$. The nonlinear heat equation was then employed, in the proof of Theorem 5.2, to deform h to a harmonic map u , with $d(u, h) = O(y^{l+\bar{\varepsilon}})$, any $\bar{\varepsilon} < \varepsilon$, so that u is asymptotically close to h , measured in the hyperbolic distance d . Clearly, u assumes the boundary values f continuously. It is natural to expect that u will also inherit the boundary regularity of h . The key to our approach, to this issue, is the following:

Lemma 6.1. *Let h and u be the maps constructed in Proposition 5.1 and Theorem 5.2, respectively. If $p \in M$ is Euclidean distance y from the boundary, then consider the representation of h and u , relative to Riemannian normal coordinates, on unit balls $B(p, 1)$ and $B(h(p), 1)$. In Hölder norm, relative to these normal coordinates, $\|u - h\|_{l+2,\varepsilon} = O(y^{l+\bar{\varepsilon}})$, any $\bar{\varepsilon} < \varepsilon$.*

Proof. Since the metrics on M and $\bar{M}$ admit transitive groups of isometries, the Christoffel symbols, and their derivatives to any order, are bounded on $B(p, 1)$ and $B(h(p), 1)$, independent of p . This may be seen by composing with isometries which move p , $h(p)$ back to fixed reference points. The usual coordinates representation of the tension field gives

$$\begin{aligned} \Delta u^\alpha + (\Gamma_{\beta\gamma}^\alpha \circ u) \frac{\partial u^\beta}{\partial x_i} \frac{\partial u^\gamma}{\partial x_j} g^{ij} &= 0, \\ \Delta h^\alpha + (\Gamma_{\beta\gamma}^\alpha \circ h) \frac{\partial h^\beta}{\partial x_i} \frac{\partial h^\gamma}{\partial x_j} g^{ij} &= \tau(h). \end{aligned}$$

Here Δ is the Laplace operator of the Riemannian metric on M . Latin indices refer to M and Greek indices refer to $\bar{M}$.

The hypotheses of Proposition 5.1, and the method of construction of h and u , show that both of these maps have bounded energy density. By Schauder theory [3], u and h are each bounded in $C^{1,\varepsilon}$. Since the coefficients of the tension field equation are now C^ε bounded, u and h are bounded in $C^{2,\varepsilon}$ norm. A standard iteration argument then bounds u and v in $C^{l+2,\varepsilon}$ norm.

We let $w = u - h$. Taking the difference of the tension field equations gives

$$\begin{aligned} \Delta w^\alpha + (\Gamma_{\beta\gamma}^\alpha \circ u) \frac{\partial w^\beta}{\partial x_i} \frac{\partial u^\gamma}{\partial x_j} g^{ij} + (\Gamma_{\beta\gamma}^\alpha \circ u) \frac{\partial h^\beta}{\partial x_i} \frac{\partial w^\gamma}{\partial x_j} g^{ij} \\ = (-\Gamma_{\beta\gamma}^\alpha \circ u + \Gamma_{\beta\gamma}^\alpha \circ h) \frac{\partial h^\beta}{\partial x_i} \frac{\partial h^\gamma}{\partial x_j} g^{ij} - \tau(h). \end{aligned}$$

This is a linear equation for w with $C^{l+1,\varepsilon}$ bounded coefficients. Since w and the inhomogeneous term are of order $O(y^{l+\bar{\varepsilon}})$, in C^0 norm, Schauder theory shows that w is $O(y^{l+\bar{\varepsilon}})$ in $C^{1,\varepsilon}$ norm. The right-hand side is now bounded, in C^ε norm, by $O(y^{l+\bar{\varepsilon}})$. Schauder theory shows that w is $O(y^{l+\bar{\varepsilon}})$ in $C^{2,\varepsilon}$ norm. Iteration yields the desired bound $\|u - h\|_{l+2,\varepsilon} = O(y^{l+\bar{\varepsilon}})$.

We apply this lemma to deduce our main result concerning boundary regularity.

Theorem 6.2. *Suppose that $f \in C^{l+2,\varepsilon}(\partial M', \partial \bar{M}')$, $0 \leq l < n_1 + 2n_2$, $0 < \varepsilon < 1$ satisfies $f_j^\gamma = 0$, $1 \leq j \leq n_1$, $\bar{n}_1 + 1 \leq \gamma \leq \bar{n}_1 + \bar{n}_2$, and $\sum_{j=n_1+1}^{n_1+n_2} \sum_{\gamma=\bar{n}_1+1}^{\bar{n}_1+\bar{n}_2} f_j^\gamma f_j^\gamma > 0$. Then there exists a harmonic map u , with boundary values f , and $u \in C^{k+1,\bar{\varepsilon}}(M', \bar{M}')$, for $-2 \leq 2k < l - 1$, any $\bar{\varepsilon} < \varepsilon$.*

Proof. Let u be the harmonic map constructed in Theorem 5.2 and h the asymptotically harmonic map of Proposition 5.1. In local Euclidean charts, near the boundaries of the compactifications, we have $|du - dh| = O(y^{l-1+\bar{\varepsilon}})$, by Lemma 6.1. The factor -1 enters because the metric (2.2) is not isotropic.

For higher derivatives, we consider the orthonormal frame field $y\partial/\partial y$, yX_i , y^2Z_j on M , with its complete Riemannian metric, and the corresponding frame field on the image $\bar{M}$. Formula (2.4), for covariant derivatives in the frame field, has constant coefficients on the right-hand side. Therefore, it is comparable to the Riemannian normal coordinate frame fields used in Lemma 6.1. It follows, by induction in k , that $|V_1 V_2 \cdots V_k(du - dh)| = O(y^{l+\bar{\varepsilon}})$, where $du - dh$ is realized as a matrix in the Riemannian orthonormal frame fields, and each V_i belongs to our chosen orthonormal frame field.

We now convert to the Euclidean reference frame $\partial/\partial y$, X_i , Z_j . If each $W_s \in \{\partial/\partial y, X_i, Z_j\}$, then $|W_1 W_2 \cdots W_k(du - dh)| = O(y^{l-1+\bar{\varepsilon}-2k})$, where $du - dh$ is realized as a matrix in the Euclidean frame. The factor 2 enters, in the exponent, because of differentiations in the directions Z_j , which correspond to $y^2 Z_j$ in the Riemannian orthonormal frame field. As long as, $2k < l - 1$, we see that u and h agree, along the boundary, up to order $k + 1$.

Suppose now that the range $\bar{M}$ is a hyperbolic space of constant negative curvature -1 . In this case, we apply similar arguments, starting with Theorem 5.4, to deduce

Theorem 6.3. *Assume that $\bar{M}$ is of constant negative curvature. Let $f \in C^{l+1,\varepsilon}(\partial M', \partial \bar{M}')$, $0 < \varepsilon < 1$, $0 \leq l < n_1 + 2n_2$, satisfy the condition*

$$\sum_{j=1}^{n_1} \sum_{\gamma=1}^{\bar{n}_1} f_j^\gamma f_j^\gamma > 0.$$

Then there exists a harmonic map u , assuming the boundary values f , and moreover $u \in C^{k+1,\bar{\varepsilon}}(M', \bar{M}')$, for $-2 \leq 2k < l - 1$, for $\bar{\varepsilon} < \varepsilon$.

If both M and $\bar{M}$ have constant negative curvature, the same argument gives a different proof of the following result from [8].

Theorem 6.4. *Suppose that the hypotheses of Theorem 6.3 are satisfied and in addition that M has constant negative curvature. Then $u \in C^{l+1,\bar{\varepsilon}}(M', \bar{M}')$, for any $\bar{\varepsilon} < \varepsilon$.*

Proof. Both the metrics on M and $\overline{M}$ are conformal to the Euclidean metrics in our local charts, by comparable factors, since $h_0^0 > 0$. Thus $|du - dh| = O(y^{l+\bar{\varepsilon}})$, in the Euclidean sense. For the higher derivatives we use $V_s \in \{y\partial/\partial y, yX_i\}$ and $W_s \in \{\partial/\partial y, X_i\}$. The factor 2, from the directions Z_j , no longer appears. Thus $|W_1 W_2 \cdots W_k(du - dh)| = O(y^{l+\bar{\varepsilon}-k})$, allowing us to choose $k \leq l$.
