THE CALABI INVARIANT AND THE EULER CLASS

TAKASHI TSUBOI

ABSTRACT. We show the following relationship between the Euler class for the group of the orientation preserving diffeomorphisms of the circle and the Calabi invariant for the group of area preserving diffeomorphisms of the disk which are the identity along the boundary. A diffeomorphism of the circle admits an extension which is an area preserving diffeomorphism of the disk. For a homomorphism ψ from the fundamental group $\langle a_1, \dots, a_{2g}; [a_1, a_2] \cdots [a_{2g-1}, a_{2g}] \rangle$ of a closed surface to the group of the diffeomorphisms of the circle, by taking the extensions $\widetilde{\psi}(a_i)$ for the generators a_i , one obtains the product $[\widetilde{\psi}(a_1), \widetilde{\psi}(a_2)] \cdots [\widetilde{\psi}(a_{2g-1}), \widetilde{\psi}(a_{2g})]$ of their commutators, and this is an area preserving diffeomorphism of the disk which is the identity along the boundary. Then the Calabi invariant of this area preserving diffeomorphism is a non-zero multiple of the Euler class of the associated circle bundle evaluated on the fundamental cycle of the surface.

INTRODUCTION

For a compact manifold M with boundary, it is interesting to investigate the relationship between the group $\text{Diff}(M)$ of the diffeomorphisms of the manifold and the group $\text{Diff}(\partial M)$ of the diffeomorphisms of its boundary.

To investigate $\text{Diff}(\partial M)$ or its subgroups, it is reasonable to impose some restrictions on the diffeomorphisms of M . The important example in mind is that the conformal diffeomorphisms of $S^{q-1} = \partial D^q$ correspond bijectively to the conformal diffeomorphisms of D^q . This shows that the condition of having an extension which is a conformal diffeomorphism of D^q is too restrictive. So we look at some milder conditions for the extension and in this paper we treat with the extensions which are volume preserving diffeomorphisms.

In fact, we look at the simplest case, namely, the relationship between the group $\text{Diff}_\Omega(D^2)$ of the area preserving diffeomorphisms of the disk and the group $\text{Diff}(S^1)_0$ of the orientation preserving diffeomorphisms of the circle.

Let $\text{Diff}_\Omega(D^2)$ denote the group of the C^∞ diffeomorphisms of the disk which preserve the volume form Ω . Here we consider the usual volume form $\Omega = dx \wedge dy$ on the unit disk D^2 . We show later that any orientation preserving diffeomorphism of the circle extends as an area preserving diffeomorphism of the disk.

Let $\Sigma_{\mathbf{g}}$ denote the closed oriented surface of genus $\mathbf{g}$. Its fundamental group has the well known presentation

$$\langle a_1, \dots, a_{2\mathbf{g}} ; [a_1, a_2] \cdots [a_{2\mathbf{g}-1}, a_{2\mathbf{g}}] \rangle.$$

Let $\psi : \pi_1(\Sigma_{\mathbf{g}}) \longrightarrow \text{Diff}(S^1)_0$ be a homomorphism, where $\text{Diff}(S^1)_0$ denotes the group of C^∞ diffeomorphisms of the circle isotopic to the identity with the C^∞ topology. Then we have the extensions $h_i \in \text{Diff}_\Omega(D^2)$ of $g_i = \psi(a_i) \in \text{Diff}(S^1)_0$ and the product $[h_1, h_2] \cdots [h_{2\mathbf{g}-1}, h_{2\mathbf{g}}]$ of commutators is an area preserving diffeomorphism of the disk which is the identity along the boundary.

Let $\text{Diff}_\Omega(D^2, \partial D^2)$ denote the group of area preserving diffeomorphisms of the disk which are the identity along the boundary. There is a homomorphism $\rho : \text{Diff}_\Omega(D^2, \partial D^2) \longrightarrow \mathbf{R}$ which is similar to that given by Calabi ([2]); see [1, Proposition II.4.3].

We prove the following theorem.

Theorem A. *Let $\psi : \pi_1(\Sigma_{\mathbf{g}}) \longrightarrow \text{Diff}(S^1)_0$ be a homomorphism, where*

$$\pi_1(\Sigma_{\mathbf{g}}) = \langle a_1, \dots, a_{2\mathbf{g}} ; [a_1, a_2] \cdots [a_{2\mathbf{g}-1}, a_{2\mathbf{g}}] \rangle.$$

Let $h_i \in \text{Diff}_\Omega(D^2)$ be an extension of $g_i = \psi(a_i)$. Then $\rho([h_1, h_2] \cdots [h_{2\mathbf{g}-1}, h_{2\mathbf{g}}])$ is a non-zero multiple of the Euler class of the associated S^1 or D^2 bundle evaluated on the fundamental class $[\Sigma_{\mathbf{g}}]$.

As a corollary to this theorem, we see that a foliated 2-disk bundle over a surface whose global holonomy is in $\text{Diff}_\Omega(D^2)$ is topologically trivial. This fact has been known by a much stronger result of Mitsumatsu ([11], [7]).

This paper is organized as follows. In §1, we give the definition of Calabi invariants. The Calabi invariants are usually considered for the group of symplectic diffeomorphisms with compact support of a symplectic manifold without boundary. In particular, in the 2-dimensional case they are considered for the group of area preserving diffeomorphisms with compact support of $\mathbf{R}^2$ or $\text{Int } D^2$. For our purpose, it is necessary to define them for the group of area preserving diffeomorphisms of D^2 . §1 consists of the verification of the formulae in [1] in our context. We define the Calabi invariant ρ on $\text{Diff}_\Omega(D^2, \partial D^2)$ and R on $\widehat{\text{Diff}}_\Omega(D^2)$, the universal covering group of $\text{Diff}_\Omega(D^2)$.

In §2, we show that for any compact manifold M , the homomorphism of the restriction from the group $\text{Diff}_\Omega(M)$ of volume preserving diffeomorphisms of M to the group $\text{Diff}(\partial M)$ of diffeomorphisms of ∂M is surjective on the identity component. This surjectivity has already been obtained by Krygin ([8]). Using Moser's homotopy ([12]), we also show that the inclusion map of the group $\text{Diff}_\Omega(M, \partial M)$ of volume preserving diffeomorphisms of M being the identity along ∂M in the group $\text{Diff}(M, \partial M)$ of diffeomorphisms of M being the identity along ∂M is a weak homotopy equivalence. Then a result of Smale ([14]) implies that $\text{Diff}_\Omega(D^2, \partial D^2)$ is contractible. This allows us to compute the difference of ρ and R .

In §3, we prove our theorem in the language of universal 2-cocycles on $\text{Diff}(S^1)$. Then this implies Theorem A. We also include a discussion on the Euler class of the foliated disk bundles with transverse invariant volume form.

I would like to thank Marco Brunella for very helpful discussions on the Calabi invariant and the Euler class. I also thank l'Institut Fourier as well as the host, Vlad Sergiescu, for their warm hospitality during my stay in the spring of 1997, where I could finish writing this paper.

1. CALABI INVARIANTS

Let D^2 denote the disk $\{(x, y) \in \mathbf{R}^2; x^2 + y^2 \leq 1\}$ with the volume form $\Omega = dx \wedge dy$. Let $\text{Diff}_\Omega(D^2, \partial D^2)$ denote the group of area preserving diffeomorphisms of the disk which are the identity along the boundary. We are going to define the homomorphism $\rho : \text{Diff}_\Omega(D^2, \partial D^2) \longrightarrow \mathbf{R}$ in the statement of Theorem A. (See [1, Proposition II.4.3] for the case of symplectic manifolds without boundary.)

Let λ be a 1-form such that $d\lambda = \Omega$. For example, for the polar coordinate (r, θ) on D^2 , put $\lambda = (r^2/2)d\theta = (1/2)(xdy - ydx)$. For an element h of $\text{Diff}_\Omega(D^2, \partial D^2)$, we look at the 1-form $h^*\lambda - \lambda$. Since $d\lambda = \Omega$, this is a closed form, we obtain a function $f(h, \lambda)$ such that $df(h, \lambda) = h^*\lambda - \lambda$.

Let $Z = \partial/\partial\theta = x(\partial/\partial y) - y(\partial/\partial x)$ be the rotational vector field. Now on ∂D ,

$$\begin{aligned} Zf(h, \lambda) &= i(Z)df(h, \lambda) = i(Z)(h^*\lambda - \lambda) \\ &= i(h_*Z)\lambda - i(Z)\lambda = i(Z)\lambda - i(Z)\lambda = 0. \end{aligned}$$

Hence we choose $f(h, \lambda)$ which is zero along the boundary. We put

$$\rho(h) = \int_{D^2} f(h, \lambda)\Omega.$$

This integral does not depend on the choice of λ ; see [4]. Note that for a function u such that $\lambda' - \lambda = du$, one obtains

$$f(h, \lambda') = f(h, \lambda) + (u \circ h - u)$$

because $(u \circ h - u)|_{\partial D^2} = 0$ for $h \in \text{Diff}_\Omega(D^2, \partial D^2)$.

It is easy to see that $\rho(h_1 h_2) = \rho(h_1) + \rho(h_2)$. Note here that

$$f(h_1 h_2, \lambda) = h_2^* f(h_1, \lambda) + f(h_2, \lambda)$$

because $f(h, \lambda)$ is zero along the boundary.

Thus we have shown the following lemma.

Lemma (1.1). $\rho : \text{Diff}_\Omega(D^2, \partial D^2) \longrightarrow \mathbf{R}$ is a homomorphism.

Note that ρ with respect to $\lambda = (r^2/2)d\theta = (1/2)(xdy - ydx)$ can be defined for an area preserving diffeomorphism whose restriction to the boundary is a rotation.

Let $\text{Diff}_\Omega(D^2)$ denote the group of the C^∞ diffeomorphisms of the disk which preserve the volume form Ω . This group is connected with respect to the C^∞ topology as we will see later (Corollary (2.6)).

There is a similar homomorphism $R : \widetilde{\text{Diff}}_\Omega(D^2) \longrightarrow \mathbf{R}$, where $\widetilde{\text{Diff}}_\Omega(D^2)$ denotes the universal covering group of $\text{Diff}_\Omega(D^2)$.

Let $\mathcal{L}_\Omega(D^2)$ denote the Lie algebra of the divergence free vector fields on the disk which are tangent to the boundary.

Lemma (1.2). For an element X of $\mathcal{L}_\Omega(D^2)$, there is a unique function f_X on D^2 such that $df_X = i(X)\Omega$ and f_X is zero on ∂D^2 .

Proof. The existence of a function f_X such that $df_X = i(X)\Omega$ is classical. Since X is tangent to the boundary, i.e., tangent to the rotational vector field Z , for the function f_X , we have

$$Zf_X = i(Z)df_X = i(Z)i(X)\Omega = 0.$$

Thus f_X is constant along the boundary. So we can choose the function f_X which is zero along the boundary. $\square$

Lemma (1.3) ([1, Lemme II.4.2]). *For $X \in \mathcal{L}_\Omega(D^2)$, let f_X denote the function on D^2 such that $df_X = i(X)\Omega$ and f_X is zero on ∂D^2 . Let $\mathcal{R} : \mathcal{L}_\Omega(D^2) \rightarrow \mathbf{R}$ be the map defined by*

$$\mathcal{R}(X) = \int_{D^2} f_X \Omega.$$

Then $\mathcal{R}$ is a surjective Lie algebra homomorphism.

In fact, note here the useful formulae ([1, Lemme II.4.2]), for $X, Y \in \mathcal{L}_\Omega(D^2)$,

$$f_{[X,Y]} = i(X)i(Y)\Omega \quad \text{and} \quad f_{[X,Y]}\Omega = df_Y \wedge df_X.$$

Thus

$$\mathcal{R}([X,Y]) = \int_{D^2} df_Y \wedge df_X = \int_{D^2} d(f_Y \wedge df_X) = \int_{\partial D^2} f_Y df_X = 0.$$

Note also that for the rotational vector field Z , $i(Z)\Omega = -rdr = d((1-r^2)/2)$ and

$$\mathcal{R}(Z) = \int_{D^2} \frac{1}{2}(1-r^2)rdrd\theta = \pi \left[\frac{r^2}{2} - \frac{r^4}{4} \right]_0^1 = \frac{\pi}{4}.$$

Now we can define $R : \widetilde{\text{Diff}}_\Omega(D^2) \rightarrow \mathbf{R}$ as in [1, Lemme II.4.1]. Let $h_t \in \text{Diff}_\Omega(D^2)$ ($t \in [0, 1]$) be a smooth path from the identity. Let X_t be the vector field defined by $X_t(x) = (\partial h_t / \partial t)(h_t^{-1}(x))$. Then X_t is an element of $\mathcal{L}_\Omega(D^2)$. For the element $[h_t] \in \widetilde{\text{Diff}}_\Omega(D^2)$, put

$$R([h_t]) = \int_0^1 \mathcal{R}(X_t) dt.$$

The verification of the well definedness of R is the same as in [1, Lemme II.4.1].

Lemma (1.4) ([1, Lemme II.4.1]). *$R : \widetilde{\text{Diff}}_\Omega(D^2) \rightarrow \mathbf{R}$ is a well-defined homomorphism.*

Note that for a full rotation T ,

$$R(T) = \int_0^1 \mathcal{R}(2\pi Z) dt = \frac{\pi^2}{2}.$$

The following lemma shows that ρ and R restricted on $\text{Diff}_\Omega(D^2, \partial D^2)$ are essentially the same. Note that we will show later that $\text{Diff}_\Omega(D^2, \partial D^2)$ is contractible (Corollary (2.6)).

Lemma (1.5) ([1, Proposition II.4.3]). *Let h_t be a path in $\text{Diff}_\Omega(D^2, \partial D^2)$ such that $h_0 = \text{id}$, then $\rho(h_1) = 2R([h_t])$.*

In fact, for $X_t(x) = (\partial h_t / \partial t)(h_t^{-1}(x))$, the function f_{X_t} satisfies the following identity ([1, Proposition II.4.3]).

$$h_1^* \lambda - \lambda = d \left(\int_0^1 h_t^* f_{X_t} dt + \int_0^1 h_t^* i(X_t) \lambda dt \right).$$

Note also the following identity ([1, Proposition II.4.3]).

$$(i(X_t)\lambda)\Omega = \lambda \wedge df_{X_t} = -d(f_{X_t}\lambda) + f_{X_t}\Omega.$$

Thus

$$\begin{aligned}
\rho(h_1) &= \int_{D^2} \left(\int_0^1 h_t^* f_{X_t} dt + \int_0^1 h_t^* i(X_t) \lambda dt \right) \Omega \\
&= \int_0^1 \left[\int_{D^2} f_{X_t} \Omega \right] dt + \int_0^1 \left[\int_{D^2} (i(X_t) \lambda) \Omega \right] dt \\
&= 2 \int_0^1 \int_{D^2} f_{X_t} \Omega dt + \int_0^1 \int_{\partial D^2} f_{X_t} \lambda dt \\
&= 2R([h_t]).
\end{aligned}$$

2. SURJECTIVITY OF $\text{Diff}_\Omega(M)_0 \rightarrow \text{Diff}(\partial M)_0$

We review here the relationship between the group of volume preserving diffeomorphisms of a compact manifold with boundary and the group of diffeomorphisms of the boundary, which is well known to the experts.

Let M be a compact oriented manifold with boundary ∂M . Let $\text{Diff}(M)$ denote the group of orientation preserving C^∞ diffeomorphisms of M with the C^∞ topology. Let $\text{Diff}_\Omega(M)$ denote the group of C^∞ diffeomorphisms of M which preserve the volume form Ω . By a result of Moser ([12]), the homomorphism $\text{Diff}_\Omega(M) \rightarrow \text{Diff}(M)$ induces a bijection on π_0 .

We look at the homomorphism $\text{Diff}_\Omega(M)_0 \rightarrow \text{Diff}(\partial M)_0$ between their identity components.

Let $\mathcal{L}_\Omega(M)$ denote the Lie algebra of the divergence free vector fields on M tangent to the boundary ∂M . The following lemma is well known.

Lemma (2.1). *For an element X of $\mathcal{L}_\Omega(M)$, there is a $(\dim(M) - 2)$ -form α_X on a neighborhood of ∂M such that $d\alpha_X = i(X)\Omega$. For a continuous family of elements $X_{(w)}$ ($w \in W$) of $\mathcal{L}_\Omega(M)$, a family of $(\dim(M) - 2)$ -forms $\alpha_{X_{(w)}}$ on a neighborhood of ∂M can be taken continuously on w .*

Lemma (2.2) ([8, Theorem 1]). *The homomorphism $\text{Diff}_\Omega(M)_0 \rightarrow \text{Diff}(\partial M)_0$ is surjective.*

Proof. For a vector field ξ on ∂M , we show that there is a divergence free vector field on M tangent to the boundary ∂M which is an extension of ξ . In fact, in a collar neighborhood $\partial M \times [0, 1]$ of $\partial M = \partial M \times \{0\}$, by a theorem of Moser ([12]), we may assume that the volume form Ω_M is of the form $\Omega_{\partial M} \wedge ds$. We define $\text{div}(\xi)$ by $\text{div}(\xi)\Omega_{\partial M} = L_\xi \Omega_{\partial M}$. We put $X(y, t) = \xi(y) - s \text{div}(\xi)(y)(\partial/\partial s)$. Then on the collar neighborhood $\partial M \times [0, 1]$,

$$\begin{aligned}
L_{X(y,t)}\Omega_M &= L_{\xi(y)}(\Omega_{\partial M} \wedge ds) - L_{s \text{div}(\xi)(y)(\partial/\partial s)}(\Omega_{\partial M} \wedge ds) \\
&= \text{div}(\xi)\Omega_{\partial M} \wedge ds - (-1)^{\dim M - 1} d(s \text{div}(\xi)(y)\Omega_{\partial M}) = 0.
\end{aligned}$$

Then in a neighborhood of ∂M , there is a $(\dim(M) - 2)$ -form α_X such that $d\alpha_X = i(X)\Omega_M$. Now we choose a smooth function μ on $\partial M \times [0, 1]$ which is 1 in a neighborhood of $\partial M = \partial M \times \{0\}$ and is 0 on a neighborhood of $\partial M \times \{1\}$. Then the vector field Y which satisfies $d(\mu\alpha_X) = i(Y)\Omega_M$ is the desired extension. Thus we proved Lemma (2.2). $\square$

In the case where $M = D^2$, we have a little more explicit expression. For a vector field $\xi = \xi(\partial/\partial\theta)$ on ∂D^2 , define a function f on $D^2 - \{O\}$ by $f(r, \theta) = (1 - r^2/2)\xi(\theta)$. Let μ be a smooth function on D^2 which is 1 in a neighborhood

of ∂D^2 and is 0 on a neighborhood of O . Then the vector field Y defined by $d(\mu f) = i(Y)\Omega$ is the desired extension.

Since we have shown that $\text{Diff}_\Omega(M)_0 \longrightarrow \text{Diff}(\partial M)_0$ is surjective, we are interested in the kernel of the homomorphism. Let $\widetilde{\text{Diff}}_\Omega(M, \partial M)_0$, $\widetilde{\text{Diff}}_\Omega(M)_0$ and $\widetilde{\text{Diff}}(\partial M)_0$ be the universal covering groups of $\text{Diff}_\Omega(M, \partial M)_0$, $\text{Diff}_\Omega(M)_0$ and $\text{Diff}(\partial M)_0$, respectively. We have the following corollary.

Corollary (2.3). *The kernel of the surjective homomorphism*

$$\widetilde{\text{Diff}}_\Omega(M)_0 \longrightarrow \widetilde{\text{Diff}}(\partial M)_0$$

coincides with $\widetilde{\text{Diff}}_\Omega(M, \partial M)_0$.

By a result of Moser ([12]), the homomorphism $\text{Diff}_\Omega(M, \partial M) \longrightarrow \text{Diff}(M, \partial M)$ induces a bijection on π_0 . The following proposition gives the information on the topology of the identity component $\text{Diff}_\Omega(M, \partial M)_0$.

Proposition (2.4). *Let M be a connected oriented manifold with non-empty boundary ∂M . The homotopy fiber of $\text{Diff}_\Omega(M, \partial M)_0 \longrightarrow \text{Diff}(M, \partial M)_0$ is contractible.*

Proof. Let $h : S^{q-1} \longrightarrow \text{Diff}_\Omega(M, \partial M)$ be a smooth map. We assume that we have a smooth extension $H : D^q \longrightarrow \text{Diff}(M, \partial M)$ of h . We construct Moser's homotopy ([12]). Let $\Omega_t^{(w)} = (1-t)H(w)^*\Omega + t\Omega$. Since M is connected and with non-empty boundary, there exists a $(\dim(M) - 1)$ -form λ such that $d\lambda = \Omega$. Note that

$$\int_M H(w)^*\Omega = \int_{\partial M} (H(w)|_{\partial M})^*\lambda = \int_{\partial M} \lambda = \int_M \Omega.$$

Put $\alpha_w = H(w)^*\lambda - \lambda$. Then $d\alpha_w = H(w)^*\Omega - \Omega$. Since $\alpha_w|_{\partial M} = 0$, on $M \times [0, 1]$ we can write

$$\alpha_w = u_w(y, t) \wedge dt + v_w(y, t)\Omega_{\partial M},$$

where $\Omega_{\partial M}$ is the volume form of ∂M and $v(y, 0) = 0$. Let $\beta_w = \alpha_w - d(\mu \cdot u_w(y, 0)t)$, where μ is a function of M which is 1 in a neighborhood of $\partial M = M \times \{0\}$ and is 0 in a neighborhood of $\partial M = M \times \{1\}$. Then $d\beta_w = H(w)^*\Omega - \Omega$ and $\beta_w(y) = 0$ for $y \in \partial M$. Let $X_t^{(w)}$ be the vector field such that $i(X_t^{(w)})\Omega_t^{(w)} = -\beta_w$. Let $\varphi_t^{(w)}$ be the diffeomorphism of M such that $(\partial\varphi_t^{(w)}/\partial t)(\varphi_t^{(w)}(x)) = X_t^{(w)}(\varphi_t^{(w)}(x))$. Then

$$\begin{aligned} (\partial/\partial t)(\varphi_t^{(w)})^*\Omega_t^{(w)} &= (\varphi_t^{(w)})^*(L_{X_t^{(w)}}\Omega_t^{(w)} + (\partial/\partial t)\Omega_t^{(w)}) \\ &= (\varphi_t^{(w)})^*(d i(X_t^{(w)})\Omega_t^{(w)} + H(w)^*\Omega - \Omega) = 0. \end{aligned}$$

Thus $(\varphi_1^{(w)})^*\Omega = H(w)^*\Omega$ for $w \in D^q$, and $(\varphi_t^{(w)})^*\Omega = \Omega$ for $w \in \partial D^q$. Put

$$H'(w) = \begin{cases} H(w/\|w\|) \circ (\varphi_{2(1-\|w\|)}^{(w/\|w\|)})^{-1} & \text{for } \|w\| \geq 1/2 \text{ and} \\ H(2w)(\varphi_1^{(2w)})^{-1} & \text{for } \|w\| \leq 1/2. \end{cases}$$

Then $H'(w) \in \text{Diff}_\Omega(M, \partial M)_0$. □

We remark here that, as A. Marin pointed out to me, Proposition (2.4) is true even if $\partial M = \emptyset$. This can be shown by obtaining α_w in the proof of Proposition (2.4), using the tensor product of topological vector spaces as in the proof of [1, Lemme II.2.2].

Proposition (2.5). *Let M be a manifold without boundary. The homotopy fiber of $\text{Diff}_\Omega(M)_0 \longrightarrow \text{Diff}(M)_0$ is contractible.*

Now we return to the group of area preserving diffeomorphism of the disk. By a result of Smale ([14]), $\text{Diff}(D^2, \partial D^2)$ is contractible. Hence we obtain the following corollary.

Corollary (2.6). *$\text{Diff}_\Omega(D^2, \partial D^2)$ is contractible.*

By this corollary, $\text{Diff}_\Omega(D^2, \partial D^2) = \widetilde{\text{Diff}}_\Omega(D^2, \partial D^2)$ coincides with the kernel of $\text{Diff}_\Omega(D^2) \longrightarrow \text{Diff}(S^1)_0$, and we have the following exact sequence of contractible topological groups

$$1 \longrightarrow \text{Diff}_\Omega(D^2, \partial D^2) \longrightarrow \widetilde{\text{Diff}}_\Omega(D^2)_0 \longrightarrow \widetilde{\text{Diff}}(S^1)_0 \longrightarrow 1.$$

Note that $\text{Diff}(S^1)_0 \simeq S^1$.

Now we can make some computation.

First note the following corollary.

Corollary (2.7). *Let h be an element of $\text{Diff}_\Omega(D^2, \partial D^2)$. For any path h_t in $\text{Diff}_\Omega(D^2, \partial D^2)$ such that $h_0 = \text{id}$ and $h_1 = h$, $\rho(h) = 2R([h_t])$.*

In the following corollaries, the path $h_t|_{\partial D^2}$ in $\text{Diff}(S^1)_0$ may not be a trivial path.

Corollary (2.8). *Let h_t be a path in $\text{Diff}_\Omega(D^2)$ such that $h_0 = \text{id}$ and $[h_t|_{\partial D^2}] = \text{id} \in \widetilde{\text{Diff}}(S^1)_0$. Then $\rho(h_1) = 2R([h_t])$.*

Proof. Let h'_t be a path in $\text{Diff}_\Omega(D^2, \partial D^2)$ such that $h'_0 = \text{id}$ and $h'_1 = h_1$. Since $h'_t|_{\partial D^2}$ is a trivial path in $\text{Diff}(S^1)$ and is homotopic to $h_t|_{\partial D^2}$, we have $[h'_t] = [h_t]$ in $\widetilde{\text{Diff}}_\Omega(D^2)$ and $R([h'_t]) = R([h_t])$. On the other hand, $\rho(h_1) = \rho(h'_1) = 2R([h'_t])$. Thus $\rho(h_1) = 2R([h_t])$. $\square$

Corollary (2.9). *Let h_t be a path in $\text{Diff}_\Omega(D^2)$ such that $h_0 = \text{id}$ and $[h_t|_{\partial D^2}] = T_k \in \widetilde{\text{Diff}}(S^1)_0$, where T_k is the translation by $k \in \mathbf{Z}$. Then $\rho(h_1) = 2R([h_t]) - k\pi^2$.*

Proof. Let h''_t be the path h_t followed by $-k$ times the full rotation. Then by the precedent corollary,

$$\rho(h_1) = \rho(h''_1) = 2R([h''_t]) = 2(R([h_t]) - k(\pi^2/2)). \quad \square$$

3. EULER CLASS

Let $\text{Diff}(S^1)_0$ denote the group of C^∞ diffeomorphisms of the circle isotopic to the identity with the C^∞ topology. Let $\widetilde{\text{Diff}}(S^1)_0$ denote the universal covering of $\text{Diff}(S^1)_0$. $\widetilde{\text{Diff}}(S^1)_0$ is the group of the periodic diffeomorphisms of the real line and there is a homomorphism $\widetilde{\text{Diff}}(S^1)_0 \longrightarrow \text{Diff}(S^1)_0$ whose kernel is $\mathbf{Z}$.

Let $\Sigma_{\mathbf{g}}$ denote the closed oriented surface of genus $\mathbf{g}$. Its fundamental group has the well known presentation

$$\langle a_1, \dots, a_{2\mathbf{g}} ; [a_1, a_2] \cdots [a_{2\mathbf{g}-1}, a_{2\mathbf{g}}] \rangle.$$

For a homomorphism $\psi : \pi_1(\Sigma_{\mathbf{g}}) \longrightarrow \text{Diff}(S^1)_0$, we take the lifts $\tilde{g}_i$ to $\widetilde{\text{Diff}}(S^1)_0$ for each $g_i = \psi(a_i)$. Then $[\tilde{g}_1, \tilde{g}_2] \cdots [\tilde{g}_{2\mathbf{g}-1}, \tilde{g}_{2\mathbf{g}}]$ is a translation by an integer. This integer is equal to $e(\psi)[\Sigma_{\mathbf{g}}]$, the Euler class of the associated circle bundle evaluated on the fundamental class of the surface (see Milnor [10] and Wood [15]).

The Euler class is also written as the cocycle defined by using a section $s : \text{Diff}(S^1)_0 \longrightarrow \widetilde{\text{Diff}}(S^1)_0$. Now for elements g_1, g_2 of $\text{Diff}(S^1)_0$, put

$$e(g_1, g_2) = s(g_1) \circ s(g_2) \circ (s(g_1 \circ g_2))^{-1} \in \mathbf{Z}.$$

Then the fact that $\mathbf{Z}$ is the center of $\widetilde{\text{Diff}}(S^1)_0$ implies that $e(g_1, g_2)$ is a 2-cocycle of the group $\text{Diff}(S^1)_0$.

We are going to show that by choosing a section $\sigma : \widetilde{\text{Diff}}(S^1)_0 \longrightarrow \widetilde{\text{Diff}}_\Omega(D^2)$, we can define a 2-cocycle of $\text{Diff}(S^1)_0$ which is cohomologous to $-\pi^2 e$. Let $p : \widetilde{\text{Diff}}_\Omega(D^2) \longrightarrow \text{Diff}_\Omega(D^2)$ denote the projection.

For elements g_1, g_2 of $\text{Diff}(S^1)_0$, put

$$c(g_1, g_2) = \rho(p(\sigma s(g_1) \circ \sigma s(g_2) \circ (\sigma s(g_1 \circ g_2))^{-1})) \in \mathbf{R}.$$

Note that $p(\sigma s(g_1) \circ \sigma s(g_2) \circ (\sigma s(g_1 \circ g_2))^{-1}) = p(\sigma s(g_1)) \circ p(\sigma s(g_2)) \circ p(\sigma s(g_1 \circ g_2))^{-1}$ is an element of $\text{Diff}_\Omega(D^2, \partial D^2)$. Now by Corollary (2.9), we see the following:

$$\begin{aligned} & \rho(p(\sigma s(g_1) \circ \sigma s(g_2) \circ (\sigma s(g_1 \circ g_2))^{-1})) \\ &= 2R(\sigma s(g_1) \circ \sigma s(g_2) \circ (\sigma s(g_1 \circ g_2))^{-1}) - \pi^2(s(g_1) \circ s(g_2) \circ (s(g_1 \circ g_2))^{-1}) \\ &= 2R(\sigma s(g_1)) + 2R(\sigma s(g_2)) - 2R(\sigma s(g_1 \circ g_2)) - \pi^2(s(g_1) \circ s(g_2) \circ (s(g_1 \circ g_2))^{-1}). \end{aligned}$$

Put $\delta(f) = 2R(\sigma s(f))$. Then we have shown the following proposition.

Proposition (3.1). $c(g_1, g_2) = \delta(\partial(g_1, g_2)) - \pi^2 e(g_1, g_2)$.

This shows that $c(g_1, g_2)$ and $-\pi^2 e(g_1, g_2)$ are cohomologous.

Now we prove Theorem A.

Proof of Theorem A. For a homomorphism $\psi : \pi_1(\Sigma_{\mathbf{g}}) \longrightarrow \text{Diff}(S^1)_0$, we have a triangulation of $\Sigma_{\mathbf{g}}$ with one vertex such that the sum of the triangles gives the fundamental class. We assume that the edges contain the generators $a_1, \dots, a_{2\mathbf{g}}$ of $\pi_1(\Sigma_{\mathbf{g}})$.

For each edge of the triangle, we have a diffeomorphism g of the circle which is the holonomy along this edge of the foliated S^1 bundle, and the extension $h \in \text{Diff}_\Omega(D^2)$ (arbitrarily chosen for edges other than $a_1, \dots, a_{2\mathbf{g}}$). Hence for a triangle with holonomies g_1, g_2 and $g_1 \circ g_2$, we have the real number $\rho(h_1 \circ h_2 \circ (h_{12})^{-1})$. The sum of them over the triangles gives $\rho([h_1, h_2] \cdots [h_{2\mathbf{g}-1}, h_{2\mathbf{g}}])$. We show that the sum does not depend on the choice of the extension. Then since the choice $p(\sigma s(g))$ gives the Euler class, another choice also gives it.

For a triangle with holonomies g_1, g_2 and $g_1 \circ g_2$, let h_1, h_2 and h_{12} , and h'_1, h'_2 and h'_{12} be the extensions of them. Then

$$\begin{aligned} & \rho(h'_1 \circ h'_2 \circ (h'_{12})^{-1}) \\ &= \rho(h'_1 \circ (h_1^{-1} \circ h_1) \circ h'_2 \circ (h_2^{-1} \circ h_1^{-1} \circ h_1 \circ h_2) \circ ((h_{12})^{-1} \circ h_{12}) \circ (h'_{12})^{-1}) \\ &= \rho((h'_1 \circ h_1^{-1}) \circ [h_1 \circ (h'_2 \circ h_2^{-1}) \circ h_1^{-1}] \\ & \quad \circ (h_1 \circ h_2 \circ (h_{12})^{-1}) \circ (h'_{12} \circ (h_{12})^{-1})^{-1}) \\ &= \rho(h'_1 \circ h_1^{-1}) + \rho(h_1 \circ (h'_2 \circ h_2^{-1}) \circ h_1^{-1}) \\ & \quad + \rho(h_1 \circ h_2 \circ (h_{12})^{-1}) + \rho((h'_{12} \circ (h_{12})^{-1})^{-1}) \\ &= \rho(h'_1 \circ h_1^{-1}) + \rho(h'_2 \circ h_2^{-1}) + \rho(h_1 \circ h_2 \circ (h_{12})^{-1}) - \rho(h'_{12} \circ (h_{12})^{-1}). \end{aligned}$$

This shows that the sum of $\rho(h'_1 \circ h'_2 \circ (h'_{12})^{-1})$ over the triangles are the same as the sum of $\rho(h_1 \circ h_2 \circ (h_{12})^{-1})$ over the triangles.

Corollary (3.2). *Let Σ_g be a closed surface of genus g . If a homomorphism $\pi_1(\Sigma_g) \longrightarrow \text{Diff}(S^1)_0$ extends as a homomorphism $\pi_1(\Sigma_g) \longrightarrow \text{Diff}_\Omega(D^2)$, then the associated S^1 or D^2 bundle is trivial.*

This fact has been known by a much stronger result of Mitsumatsu ([11], [7]) which says that if a foliated D^n bundle over an n dimensional manifold admits a transversely invariant measure whose support consists of more than one point transversely, then its Euler class is zero.

In our case, this fact for a flat $\text{Diff}_\Omega(D^n)_0$ bundle can also be shown as follows. Consider the Thom class of the disk bundle $E \longrightarrow M$. Since the Thom class is characterized by the fact that the restriction to the fiber $(D^n, \partial D^n)$ is the generator of $H^n(D^n, \partial D^n)$. When there is a transverse invariant volume form, then we can give a Thom form Φ which is locally the volume form of the fiber in each foliated chart. Then it is clear that $\Phi \wedge \Phi = 0$. Since the Euler class e satisfies $[\Phi \wedge \Phi] = [\Phi] \cup \text{proj}^* e$, and $[\Phi] \cup : H^*(M) \longrightarrow H^{*+n}(E, \partial E)$ is isomorphic, $\text{proj}^* e = 0$, hence $e = s^* \text{proj}^* e = 0$. Thus the Euler class e is zero.

In view of this corollary, it is interesting to investigate the expression of the Euler class for the foliated sphere bundle in terms of the volume preserving extensions of its holonomy. In other words, it is interesting to look for a result similar to our main theorem for some cohomology classes of groups $\text{Diff}(S^{q-1})_0$ and $\text{Diff}_\Omega(D^q)_0$.

The Euler class is defined for topological sphere bundles. In our case it is defined as a 2-dimensional cohomology class of the group $\text{Homeo}(S^1)_0$. Hence it is interesting to know about homology groups of the group $\text{Homeo}_\Omega(D^2)_0$ of measure preserving homeomorphisms. For the group of homeomorphisms of a compact manifold of dimension greater than 2 which preserve the Lebesgue measure, by using a result of Oxtoby and Ulam ([13]), Fathi calculated its abelianization ([3]). The abelianization of $\text{Homeo}_\Omega(D^2)_0$ or $\text{Homeo}_\Omega(D^2, \partial D^2)$ is not known.
