# OPTIMAL FACTORIZATION OF MUCKENHOUPT WEIGHTS 

MICHAEL BRIAN KOREY

#### Abstract

Peter Jones' theorem on the factorization of $A_{p}$ weights is sharpened for weights with bounds near 1, allowing the factorization to be performed continuously near the limiting, unweighted case. When $1<p<\infty$ and $w$ is an $A_{p}$ weight with bound $A_{p}(w)=1+\varepsilon$, it is shown that there exist $A_{1}$ weights $u, v$ such that both the formula $w=u v^{1-p}$ and the estimates $A_{1}(u), A_{1}(v)=1+\mathcal{O}(\sqrt{\varepsilon})$ hold. The square root in these estimates is also proven to be the correct asymptotic power as $\varepsilon \rightarrow 0$.

## 1. Introduction

A non-negative weight function $w$ on $\mathbb{R}^{n}$ is in the Muckenhoupt $A_{p}$ class, $w \in A_{p}$, if there is a constant $C$ such that

$$
\begin{equation*}
\left(\frac{1}{|Q|} \int_{Q} w\right)\left(\frac{1}{|Q|} \int_{Q} w^{1 /(1-p)}\right)^{p-1} \leq C \tag{1}
\end{equation*}
$$

for all cubes $Q$ in $\mathbb{R}^{n}$ with sides parallel to the coordinate axes. Here and throughout this note $|Q|$ denotes the Lebesgue measure of $Q$, integrals are evaluated with respect to Lebesgue measure, and $1<p<\infty$. The smallest constant $C$ for which (11) holds is termed the $A_{p}$ bound of $w$ and is denoted $A_{p}(w)$; note that $A_{p}(w) \geq 1$, by Hölder's inequality, with equality only when $w$ is almost everywhere constant. The limiting case $w \in A_{1}$ is defined by the requirement that

$$
\begin{equation*}
\frac{1}{|Q|} \int_{Q} w \leq C \inf _{Q} w \tag{2}
\end{equation*}
$$

for all cubes $Q$, where $\inf _{Q} w$ denotes the essential infimum of $w$ over $Q .1$ The least bound $C$ in (2), denoted $A_{1}(w)$, is likewise at least 1.

Products of suitable powers of $A_{1}$ weights are in $A_{p}$. In fact, if $u$ and $v$ are in $A_{1}$, then $u v^{1-p}$ is in $A_{p}$, and the bound of this product satisfies the estimate

$$
\begin{equation*}
A_{p}\left(u v^{1-p}\right) \leq A_{1}(u) A_{1}(v)^{p-1} \tag{3}
\end{equation*}
$$

as follows directly from conditions (1) and (2). By means of a delicate stoppingtime argument, Jones [6] succeeded in proving the converse: each $A_{p}$ weight $w$ can be decomposed as the product $w=u v^{1-p}$ of $A_{1}$ weights $u$ and $v$. Several years later, Rubio de Francia found a much simpler proof of this decomposition (see [2], [12], and [13]), and his "reiteration" scheme has since found many applications. It

[^0]has been used, for example, to give a constructive proof of the duality of Hardy space $H^{1}$ and BMO, the space of functions of bounded mean oscillation (see [3]); to prove an extrapolation theorem for operators on weighted $L^{p}$ spaces (see [12]); and to characterize the domains on which BMO functions have extensions to all $\mathbb{R}^{n}$ (see [5]).

For the purpose to be discussed here, however, the reiteration argument has one shortcoming: it does not give sharp quantitative information on the weight bounds $A_{1}(u)$ and $A_{1}(v)$ of the factors that arise in the decomposition of a given $A_{p}$ weight $w$ as $u v^{1-p}$. In particular, it does not reveal whether it is possible to factor $A_{p}$ weights with bounds near 1 "continuously" into pairs of component weights with $A_{1}$ bounds near 1. By contrast, the estimate (3) immediately shows that when the bounds $A_{1}(u)$ and $A_{1}(v)$ are near 1 , then so is $A_{p}\left(u v^{1-p}\right)$.

To see how this difficulty arises, let us briefly review the reiteration argument in the simplest case $p=2$, in which we seek to factor a given $A_{2}$ weight $w$ into a quotient of two $A_{1}$ weights (see [15]).

Since $w \in A_{2}$, the Hardy-Littlewood maximal operator $M$ is bounded both on $L^{2}(w d x)$ and, by the symmetry in (1), on $L^{2}\left(w^{-1} d x\right)^{2}$ It follows that the sublinear operator $S$ defined by

$$
S(f)=w^{-1 / 2} M\left(w^{1 / 2} f\right)+w^{1 / 2} M\left(w^{-1 / 2} f\right)
$$

is bounded on the unweighted space $L^{2}(d x)$, say $\|S(f)\|_{2} \leq B\|f\|_{2}$. Now choose a positive function $f$ in $L^{2}(d x)$, as well as a number $\lambda$ larger than 1 . Next, set $g=\sum_{k=1}^{\infty}(\lambda B)^{-k} S^{k}(f)$. Then $g \in L^{2}(d x)$ and

$$
S(g)=(\lambda B) \sum_{k=2}^{\infty}(\lambda B)^{-k} S^{k}(f)=(\lambda B) g-S(f)
$$

Since $S(f) \geq 0$, the pointwise estimate $S(g) \leq(\lambda B) g$ holds. Thus

$$
w^{-1 / 2} M\left(w^{1 / 2} g\right) \leq S(g) \leq(\lambda B) g
$$

so that $M\left(w^{1 / 2} g\right) \leq \lambda B\left(w^{1 / 2} g\right)$. Hence $u=w^{1 / 2} g$ belongs to $A_{1}$ and satisfies $A_{1}(u) \leq \lambda B$. Similarly, $v=w^{-1 / 2} g$ is in $A_{1}$, and $A_{1}(v) \leq \lambda B$. The construction thus quickly decomposes $w$ as a quotient $u / v$ of two $A_{1}$ weights; it does not, however, sharply control the $A_{1}$ bounds of the factors in this quotient. For even if the $A_{2}$ bound of the original weight $w$ is near 1 , we can only conclude from the above argument (letting $\lambda$ approach 1) that the $A_{1}$ bounds of $u$ and $v$ are no larger than the operator bound $B$, and this is at least $2 \sqrt[3]{3}$

Thus, the reiteration scheme, while useful in numerous applications, does not answer the question we pose here: if $A_{2}(w)$ is near 1 , then is it possible to factor $w$ as a quotient of two $A_{1}$ weights $u$ and $v$ with bounds also near 1? The affirmative answer to this question is contained in the following theorem, the proof of which is the focus of this paper.

[^1]Theorem. If $w$ is an $A_{p}$ weight and $A_{p}(w)=1+\varepsilon<1+\varepsilon_{0}$, then there exist $A_{1}$ weights $u$ and $v$ satisfying both $w=u v^{1-p}$ and

$$
\begin{equation*}
A_{1}(u) \leq 1+C \sqrt{\varepsilon}, \quad A_{1}(v) \leq 1+C \sqrt{\varepsilon} \tag{4}
\end{equation*}
$$

The constants $C$ and $\varepsilon_{0}$ depend only on the dimension $n$ and the index $p$.
The method of the proof is first to supplement the original argument of Jones [6] in the dyadic model case with some sharp estimates in the author's thesis 8]. The averaging method of Garnett and Jones [4] is then adapted to handle the general case. Sharpness of the asymptotic estimate (4) in the theorem is shown in the final section.

## 2. The dyadic setting

We begin by proving the following dyadic version of the factorization theorem. This version is stated for the collection $\mathcal{D}\left(Q_{0}\right)$ of all dyadic subcubes of an arbitrary, fixed cube $Q_{0}$ in $\mathbb{R}^{n}$ : that is, all those cubes obtained by dividing $Q_{0}$ into $2^{n}$ congruent cubes of half its length, dividing each of these into $2^{n}$ congruent cubes, and so on. By convention, $Q_{0}$ itself belongs to $\mathcal{D}\left(Q_{0}\right)$.

Lemma 1. Suppose that $w$ satisfies the dyadic $A_{p}$ condition

$$
\begin{equation*}
\sup _{Q \in \mathcal{D}\left(Q_{0}\right)}\left(\frac{1}{|Q|} \int_{Q} w\right)\left(\frac{1}{|Q|} \int_{Q} w^{1 /(1-p)}\right)^{p-1}=1+\varepsilon \leq 1+\varepsilon_{0} \tag{5}
\end{equation*}
$$

on the cube $Q_{0}$. Let $f=\log w$. Then there exist functions $g, F$, and $G$ on $Q_{0}$ that satisfy both the pointwise identity

$$
\begin{equation*}
f(x)-f_{Q_{0}}=g(x)+F(x)-G(x), \quad x \in Q_{0} \tag{6}
\end{equation*}
$$

and the estimates

$$
\begin{align*}
|g| & \leq C_{1} \sqrt{\varepsilon}  \tag{7}\\
\frac{1}{|Q|} \int_{Q} e^{F} & \leq\left(1+C_{1} \sqrt{\varepsilon}\right) \inf _{Q} e^{F}, \quad Q \in \mathcal{D}\left(Q_{0}\right)  \tag{8}\\
\frac{1}{|Q|} \int_{Q} e^{G /(p-1)} & \leq\left(1+C_{1} \sqrt{\varepsilon}\right) \inf _{Q} e^{G /(p-1)}, \quad Q \in \mathcal{D}\left(Q_{0}\right) \tag{9}
\end{align*}
$$

The constants $C_{1}$ and $\varepsilon_{0}$ depend only on the dimension $n$ and the index $p$.
Essential to the estimates in the lemma is the following measure-theoretic result (see [8], [9], or [11]), which insures that the mean oscillation of the logarithm of a weight is close to 0 when the $A_{p}$ bound of the weight is near the optimal value 1 .

Lemma 2. If the ratio of the arithmetic and geometric means of $w$ on $Q$ satisfies

$$
\left(\frac{1}{|Q|} \int_{Q} w\right) / \exp \left(\frac{1}{|Q|} \int_{Q} \log w\right)=1+\varepsilon<2
$$

and $f=\log w$, then

$$
\begin{equation*}
\frac{1}{|Q|} \int_{Q}\left|f-f_{Q}\right| \leq C_{2} \sqrt{\varepsilon} \tag{10}
\end{equation*}
$$

This result holds on each single cube (and, in fact, we may take $C_{2}=32$ ). The form in which we shall apply the estimate is as follows: Let $\|\cdot\|$ and $\|\cdot\|_{*}$ denote the dyadic and full BMO seminorms, i.e.,

$$
\|f\|=\sup _{Q \in \mathcal{D}\left(Q_{0}\right)} \frac{1}{|Q|} \int_{Q}\left|f-f_{Q}\right| \quad \text { and } \quad\|f\|_{*}=\sup _{Q \subset \mathbb{R}^{n}} \frac{1}{|Q|} \int_{Q}\left|f-f_{Q}\right|
$$

When $w$ satisfies the dyadic $A_{p}$ condition (5), then Jensen's inequality and (10) insure that $\|\log w\| \leq C_{2} \sqrt{\varepsilon}$; likewise, when $A_{p}(w)=1+\varepsilon$, then $\|\log w\|_{*} \leq C_{2} \sqrt{\varepsilon}$.

The following proof of the dyadic version of the factorization theorem combines an iterative Calderón-Zygmund decomposition singling out those cubes on which the mean oscillation of $f$ is large with the bound obtained from Lemma $2^{4}$

Proof of Lemma 1. Fix $Q_{0}$, set $f=\log w$ and $\lambda=2^{n}\|f\|$. Let $\mathcal{G}^{0}=\left\{Q_{0}\right\}$. Define

$$
\begin{equation*}
\mathcal{G}^{1}=\left\{Q_{j} \in \mathcal{D}\left(Q_{0}\right):\left|f_{Q_{j}}-f_{Q_{0}}\right|>\lambda, Q_{j} \text { maximal }\right\} \tag{11}
\end{equation*}
$$

and, inductively,

$$
\begin{equation*}
\mathcal{G}^{m+1}=\left\{Q_{j} \in \mathcal{D}(Q): Q \in \mathcal{G}^{m},\left|f_{Q_{j}}-f_{Q}\right|>\lambda, Q_{j} \text { maximal }\right\} \tag{12}
\end{equation*}
$$

Write $\mathcal{G}=\bigcup_{m=0}^{\infty} \mathcal{G}^{m}$ and let $\Omega^{m}$ be the union of the cubes in $\mathcal{G}^{m}$. By construction, $\Omega^{m+1} \subseteq \Omega^{m} \subseteq \cdots \subseteq \Omega^{0}$. For $Q$ in $\mathcal{G}^{m+1}$, let $\widetilde{Q}$ denote the unique cube in $\mathcal{G}^{m}$ containing $Q$.

Now, maximality in the selection criteria (11) and (12) and standard BMO estimates give rise to the mean-value inequality

$$
\begin{equation*}
\lambda<\left|f_{Q}-f_{\widetilde{Q}}\right| \leq 2 \lambda, \quad Q \in \bigcup_{m=1}^{\infty} \mathcal{G}^{m} \tag{13}
\end{equation*}
$$

They also lead to the relative density estimate

$$
\begin{equation*}
\left|Q \cap \Omega^{m+1}\right| \leq 2^{-n}|Q|, \quad Q \in \mathcal{G}^{m} \tag{14}
\end{equation*}
$$

which is valid for each non-negative integer $m$. Summing this last estimate over the cubes in $\mathcal{G}^{m}$ and iterating leads to the bound

$$
\begin{equation*}
\left|\Omega^{m}\right| \leq 2^{-m n}\left|\Omega^{0}\right| \tag{15}
\end{equation*}
$$

Furthermore, differentiation of the Lebesgue integral-in conjunction with (11) and (12) -yields the pointwise estimate

$$
\begin{equation*}
\left|f(x)-\sum_{Q_{j} \in \mathcal{G}^{m}} f_{Q_{j}} \chi_{Q_{j}}(x)\right| \leq \lambda, \quad x \in \Omega^{m} \backslash \Omega^{m+1} \tag{16}
\end{equation*}
$$

which is also valid for each non-negative $m$. Hence, when we set

$$
\begin{equation*}
g(x)=f(x)-f_{Q_{0}}-\sum_{m=1}^{\infty} \sum_{Q_{j} \in \mathcal{G}^{m}}\left(f_{Q_{j}}-f_{\widetilde{Q}_{j}}\right) \chi_{Q_{j}}(x), \tag{17}
\end{equation*}
$$

then $|g| \leq \lambda$ a.e. on $Q_{0} 5$ The bound $\lambda=2^{n}\|f\| \leq 2^{n} C_{2} \sqrt{\varepsilon}$ from Lemma 2 then gives the desired estimate (7) for $g$.

[^2]Next, to obtain suitable dyadic $A_{1}$ factors of $w$, split the double sum in (17) according to the sign of the difference $f_{Q_{j}}-f_{\widetilde{Q}_{j}}$. That is, let

$$
f(x)-f_{Q_{0}}=g(x)+F(x)-G(x)
$$

where

$$
\begin{equation*}
F(x)=\sum_{m=1}^{\infty} \sum_{Q_{j} \in \mathcal{G}^{m}}\left(f_{Q_{j}}-f_{\widetilde{Q}_{j}}\right)^{+} \chi_{Q_{j}}(x) \tag{18}
\end{equation*}
$$

and

$$
\begin{equation*}
G(x)=\sum_{m=1}^{\infty} \sum_{Q_{j} \in \mathcal{G}^{m}}\left(f_{\widetilde{Q}_{j}}-f_{Q_{j}}\right)^{+} \chi_{Q_{j}}(x) \tag{19}
\end{equation*}
$$

It is important to note that the functions $F$ and $G$ defined in (18) and (19) are non-negative; where they are positive, their value must, by (13), exceed $\lambda$. For later purposes, we also wish to express $F$ and $G$ as sums over all the dyadic subcubes of $Q_{0}$, not just over those where the mean oscillation of $f$ is large. Thus, we write

$$
\begin{equation*}
F(x)=\sum_{Q_{k} \in \mathcal{D}\left(Q_{0}\right)} a_{k} \chi_{Q_{k}}(x) \tag{20}
\end{equation*}
$$

and

$$
\begin{equation*}
G(x)=\sum_{Q_{k} \in \mathcal{D}\left(Q_{0}\right)} b_{k} \chi_{Q_{k}}(x) \tag{21}
\end{equation*}
$$

In (20), for example, whenever $Q_{k} \notin \bigcup_{m=1}^{\infty} \mathcal{G}^{m}$ or whenever $Q_{k} \in \bigcup_{m=1}^{\infty} \mathcal{G}^{m}$ but $f_{Q_{k}}-f_{\widetilde{Q}_{k}} \leq \lambda$, then $a_{k}=0$; otherwise, $a_{k}=f_{Q_{k}}-f_{\widetilde{Q}_{k}}$. A similar interpretation applies to the coefficients $b_{k}$.

In light of Lemma 2, it suffices to show that the dyadic $A_{1}$ bounds of $\exp F$ and $\exp [G /(p-1)]$ do not exceed $1+C \lambda$, provided that $\lambda=2^{n}\|f\|$ is suitably small. This means we must show that

$$
\begin{equation*}
\frac{1}{|Q|} \int_{Q} e^{F} \leq(1+C \lambda) \inf _{Q} e^{F} \tag{22}
\end{equation*}
$$

and

$$
\begin{equation*}
\frac{1}{|Q|} \int_{Q} e^{G /(p-1)} \leq(1+C \lambda) \inf _{Q} e^{G /(p-1)} \tag{23}
\end{equation*}
$$

for all $Q \in \mathcal{D}\left(Q_{0}\right)$. To prove this we now consider three cases.
Case I: The initial cube. We first verify (22) in the case when $Q=Q_{0}$, the original cube. In this case, $\inf _{Q} F=0$, for the choice of $\lambda$ in the stopping-time argument insures that the set $\Omega^{0} \backslash \Omega^{1}$ has positive measure; see (15). Changing variables in the standard integral formula $\int_{Q}\left(e^{F}-1\right)=\int_{0}^{\infty} e^{t}|\{x \in Q: F(x)>t\}| d t$ leads to the equation

$$
\begin{equation*}
\frac{1}{|Q|} \int_{Q} e^{F}=1+\frac{\lambda}{|Q|} \int_{0}^{\infty}\left|E_{\tau}\right| e^{\lambda \tau} d \tau \tag{24}
\end{equation*}
$$

in which

$$
E_{\tau}=\{x \in Q: F(x)>\lambda \tau\}
$$

Estimating the dyadic $A_{1}$ bound of $\exp F$ then reduces to estimating the size of the set $E_{\tau}$. But condition (13) insures that $E_{\tau} \subseteq \Omega^{1}$, when $0 \leq \tau<2$, and, in general, that $E_{\tau} \subseteq \Omega^{k}$, when $2(k-1) \leq \tau<2 k$ (for each $k$ in $\mathbb{N}$ ). Thus, by (15) and (24),

$$
\begin{equation*}
\frac{1}{|Q|} \int_{Q} e^{F} \leq 1+2 \lambda \sum_{k=1}^{\infty} \frac{\left|\Omega^{k}\right|}{|Q|} e^{2 \lambda k} \leq 1+2 \lambda \sum_{k=1}^{\infty} 2^{-n k} e^{2 \lambda k} \tag{25}
\end{equation*}
$$

The latter sum is less than 2 , when $\lambda=2^{n}\|f\|$ is sufficiently small. Consequently, $|Q|^{-1} \int_{Q} e^{F} \leq 1+4 \lambda$, which is (22) for $Q=Q_{0}$.

Case II: A cube with a large jump in mean value. Suppose now that $Q \in \mathcal{G}^{m}$ for some positive $m$ and that $f_{Q}-f_{\widetilde{Q}}>\lambda \sqrt[6]{6}$ Then

$$
\left(\inf _{Q} e^{F}\right)^{-1} \frac{1}{|Q|} \int_{Q} e^{F}=\frac{1}{|Q|} \int_{Q} e^{F-\inf _{Q} F}=1+\frac{\lambda}{|Q|} \int_{0}^{\infty}\left|\widetilde{E}_{\tau}\right| e^{\lambda \tau} d \tau
$$

where

$$
\widetilde{E}_{\tau}=\left\{x \in Q: F(x)-\inf _{Q} F>\lambda \tau\right\}
$$

In analogy to the first case, we find from (13) and (16) that $\widetilde{E}_{\tau} \subset Q \cap \Omega^{m+k}$, when $2(k-1) \leq \tau<2 k$ (for each $k$ in $\mathbb{N}$ ). So for $\tau$ in this range, $\left|\widetilde{E}_{\tau}\right| \leq 2^{-n k}|Q|$, from which the desired estimate (22) once again follows.

Case III: Cubes with no large jump in the mean. In Case I, we considered $Q_{0}$; in Case II, we treated those dyadic cubes $Q$ within $Q_{0}$ for which $f_{Q}-f_{\widetilde{Q}}>\lambda$. To handle the remaining case efficiently, we first introduce a bit of further notation: for each proper dyadic subcube $Q$ of $Q_{0}$, let $\widetilde{Q}$ denote the minimal cube in $\mathcal{G}$ that strictly contains it ${ }^{77}$ and set

$$
\begin{aligned}
\mathcal{P}(Q) & =\left\{Q_{j} \in \mathcal{D}(Q): f_{Q_{j}}-f_{\widetilde{Q}}>\quad \lambda, Q_{j} \text { maximal }\right\} \\
\mathcal{N}(Q) & =\left\{Q_{j} \in \mathcal{D}(Q): f_{Q_{j}}-f_{\widetilde{Q}}<-\lambda, Q_{j} \text { maximal }\right\}
\end{aligned}
$$

Note that the union of $\mathcal{P}(Q)$ and $\mathcal{N}(Q)$ is exactly the set of the cubes in $\bigcup_{m=1}^{\infty} \mathcal{G}^{m}$ that lie within $Q$. In this notation, the remaining case now consists of proving (22) on each dyadic cube $Q$ for which $Q \notin \mathcal{P}(Q)$.

Fix such a cube $Q$. To estimate $\int_{Q} \exp F$ we split $Q$ into the union of its subcubes in $\mathcal{P}(Q)$ and the complement of this union. On the one hand, if $Q_{j} \in \mathcal{P}(Q)$, then $\widetilde{Q}_{j}=\widetilde{Q} ;$ Case II then applies, so that

$$
\int_{Q_{j}} e^{F} \leq(1+4 \lambda)\left(\inf _{Q_{j}} e^{F}\right)\left|Q_{j}\right|
$$

But $\inf _{Q_{j}} F=\inf _{\widetilde{Q}} F+\left(f_{Q_{j}}-f_{\widetilde{Q}_{j}}\right)$, hence

$$
\lambda<\inf _{Q_{j}} F-\inf _{\widetilde{Q}} F=f_{Q_{j}}-f_{\widetilde{Q}_{j}} \leq 2 \lambda
$$

[^3]by (13). On the other hand, on the complement in $Q$ of $\bigcup Q_{j}$ the value of $F$ is exactly $\inf _{\widetilde{Q}} F$. All together, then,
\[

$$
\begin{aligned}
\int_{Q} e^{F} & \leq(1+4 \lambda) \sum_{Q_{j} \in \mathcal{P}(Q)}\left(\inf _{Q_{j}} e^{F}\right)\left|Q_{j}\right|+\left(\inf _{\widetilde{Q}} e^{F}\right)\left|Q \backslash \bigcup_{Q_{j} \in \mathcal{P}(Q)} Q_{j}\right| \\
& \leq(1+4 \lambda) e^{2 \lambda}\left(\inf _{\widetilde{Q}} e^{F}\right) \sum_{Q_{j} \in \mathcal{P}(Q)}\left|Q_{j}\right|+\left(\inf _{\widetilde{Q}} e^{F}\right)\left|Q \backslash \bigcup_{Q_{j} \in \mathcal{P}(Q)} Q_{j}\right| \\
& \leq(1+4 \lambda) e^{2 \lambda}\left(\inf _{\widetilde{Q}} e^{F}\right)|Q|
\end{aligned}
$$
\]

Since $\inf _{\widetilde{Q}} F \leq \inf _{Q} F$, the bound (221) thus also holds for the cubes $Q$ in this, the last case.

The justification of the dyadic $A_{1}$ bound (23) is similar, with $G /(p-1)$ in place of $F, \mathcal{N}(Q)$ in place of $\mathcal{P}(Q)$, etc. This completes the proof of Lemman.

## 3. The general setting

The proof of the theorem follows the argument in [4, pp. 361-364], except for certain technical modifications which are introduced to keep all bounds as small as possible. For completeness, the full proof is given here. Let $S_{N}$ be the cube $\left\{x \in \mathbb{R}^{n}:\left|x_{i}\right| \leq 2^{N}, 1 \leq i \leq n\right\}$.

Lemma 3. Suppose that $w \in A_{p}$ and that $A_{p}(w)=1+\varepsilon<1+\varepsilon_{0}$. Let $f=\log w$. For each natural number $N$ there exist functions $g_{N}, F_{N}$, and $G_{N}$ on the cube $S_{N}$ satisfying both the pointwise identity

$$
\begin{equation*}
f(x)-f_{S_{N}}=g_{N}(x)+F_{N}(x)-G_{N}(x), \quad x \in S_{N} \tag{26}
\end{equation*}
$$

and the bounds

$$
\begin{align*}
\left|g_{N}\right| & \leq C_{3} \sqrt{\varepsilon},  \tag{27}\\
\frac{1}{|Q|} \int_{Q} e^{F_{N}} & \leq\left(1+C_{3} \sqrt{\varepsilon}\right) \inf _{Q} e^{F_{N}}, \quad Q \subseteq S_{N}  \tag{28}\\
\frac{1}{|Q|} \int_{Q} e^{G_{N} /(p-1)} & \leq\left(1+C_{3} \sqrt{\varepsilon}\right) \inf _{Q} e^{G_{N} /(p-1)}, \quad Q \subseteq S_{N} \tag{29}
\end{align*}
$$

The constants $C_{3}$ and $\varepsilon_{0}$ depend only on the dimension $n$ and the index $p$.
Note that (28) and (29) are valid for all (not just dyadic) subcubes of $S_{N}$.
Let us first show how this last lemma implies the theorem. The identity (26) can be re-written, after subtracting off the mean value of each side on $S_{0}$, as

$$
\begin{align*}
f(x)-f_{S_{0}} & =\left[g_{N}(x)-\left(g_{N}\right)_{S_{0}}\right]+\left[F_{N}(x)-\left(F_{N}\right)_{S_{0}}\right]-\left[G_{N}(x)-\left(G_{N}\right)_{S_{0}}\right]  \tag{30}\\
& =\tilde{g}_{N}(x)+\tilde{F}_{N}(x)-\tilde{G}_{N}(x) \tag{31}
\end{align*}
$$

Then $\left|\tilde{g}_{N}\right| \leq 2 C_{3} \sqrt{\varepsilon}$ a.e. on $S_{N}$, by (27). Taking the logarithm of (28) readily yields a bound on the mean oscillation of $F_{N}$ :

$$
\begin{equation*}
\frac{1}{|Q|} \int_{Q}\left|F_{N}-\left(F_{N}\right)_{Q}\right| \leq \frac{2}{|Q|} \int_{Q}\left(F_{N}-\inf _{Q} F_{N}\right) \leq 2 C_{3} \sqrt{\varepsilon}, \quad Q \subseteq S_{N} \tag{32}
\end{equation*}
$$

The same estimate applies to $\tilde{F}_{N}$, since it differs from $F_{N}$ only by an additive constant. The John-Nirenberg inequality in [7] then allows us to convert this statement
into a bound on the quadratic mean oscillation of $\tilde{F}_{N}$, namely

$$
\frac{1}{|Q|} \int_{Q}\left|\tilde{F}_{N}-\left(\tilde{F}_{N}\right)_{Q}\right|^{2} \leq C^{\prime} \varepsilon, \quad Q \subseteq S_{N}
$$

Suppose now that $M \leq N$. When $Q=S_{M}$, the last estimate becomes

$$
\begin{equation*}
\frac{1}{\left|S_{M}\right|} \int_{S_{M}}\left|\tilde{F}_{N}\right|^{2} \leq C^{\prime} \varepsilon+\left|\left(\tilde{F}_{N}\right)_{S_{M}}\right|^{2} \tag{33}
\end{equation*}
$$

To control the right-hand side, form a telescoping sum of mean values:

$$
\begin{equation*}
\left(\tilde{F}_{N}\right)_{S_{M}}=\left(\tilde{F}_{N}\right)_{S_{0}}+\left[\left(\tilde{F}_{N}\right)_{S_{1}}-\left(\tilde{F}_{N}\right)_{S_{0}}\right]+\cdots+\left[\left(\tilde{F}_{N}\right)_{S_{M}}-\left(\tilde{F}_{N}\right)_{S_{M-1}}\right] \tag{34}
\end{equation*}
$$

Since $\left|S_{1}\right| /\left|S_{0}\right|=\cdots=\left|S_{M}\right| /\left|S_{M-1}\right|=2^{n}$, the magnitude of each of the $M$ bracketed differences is no more than the fixed quantity $2^{n}\left(C_{3} \sqrt{\varepsilon}\right)$, by (32). In fact, as $\left(\tilde{F}_{N}\right)_{S_{0}}=0$, (34) becomes $\left|\left(F_{N}\right)_{S_{M}}\right| \leq M 2^{n} C_{3} \sqrt{\varepsilon}$. Conditions (33) and (34) together then yield the quadratic bound

$$
\frac{1}{\left|S_{M}\right|} \int_{S_{M}}\left|\tilde{F}_{N}\right|^{2} \leq C^{\prime} \varepsilon+\left(M 2^{n} C_{3} \sqrt{\varepsilon}\right)^{2}<\infty
$$

which holds uniformly for $N=M, M+1, M+2, \ldots$, and an analogous bound is also valid for $\tilde{G}_{N}$. For each $M$, the sequences $\left\{\tilde{F}_{N}: N \geq M\right\}$ and $\left\{\tilde{G}_{N}: N \geq M\right\}$ are thus bounded in $L^{2}\left(S_{M}\right)$; we have also already seen that $\left\{\tilde{g}_{N}: N \geq M\right\}$ is a bounded sequence in $L^{\infty}\left(S_{N}\right)$. Using a diagonal argument, we may therefore choose a subsequence $N_{j} \rightarrow \infty$, so that $\tilde{F}_{N_{j}} \rightharpoonup F, \quad \tilde{G}_{N_{j}} \rightharpoonup G$ weakly in $L^{2}\left(S_{M}\right)$ and so that $\tilde{g}_{N_{j}} \rightharpoonup g$ in the weak-star topology on $L^{\infty}\left(S_{M}\right)$, with this convergence holding simultaneously for all $M{ }^{8}$ Moreover, on each cube $S_{M}$ there is a sequence of finite convex combinations $\sum_{j=1}^{J} t_{j} \widetilde{F}_{N_{j}}$, with $t_{j} \geq 0$ and $\sum_{j=1}^{J} t_{j}=1$, that converges to $F$ both in $L^{2}$ and (taking a further subsequence, if necessary) pointwise a.e 9 From (31), then, $f(x)-f_{S_{0}}=g(x)+F(x)-G(x)$, with

$$
\begin{equation*}
|g| \leq C_{3} \sqrt{\varepsilon} \quad \text { a.e. on } \mathbb{R}^{n} \tag{35}
\end{equation*}
$$

To obtain the desired $A_{1}$ bound on $\exp F$, fix an arbitrary cube $Q$ in $\mathbb{R}^{n}$, and choose $M$ so large that $Q \subseteq S_{M}$. Apply Fatou's lemma and Hölder's inequality to the sequence $\left\{\exp \sum_{j=1}^{J} t_{j} \tilde{F}_{N_{j}}: N_{j} \geq M\right\}$ to obtain the bound 10

$$
\begin{equation*}
\frac{1}{|Q|} \int_{Q} e^{F} \leq \lim \inf _{J \rightarrow \infty} \prod_{j=1}^{J}\left(\frac{1}{|Q|} \int_{Q} e^{\tilde{F}_{N_{j}}}\right)^{t_{j}} \leq\left(1+C_{3} \sqrt{\varepsilon}\right) \inf _{Q} e^{F} \tag{36}
\end{equation*}
$$

from (28). Set $u=\exp \left[f_{S_{0}}+g+F\right]$. Thanks to (35) and (36), $u \in A_{1}$ and $A_{1}(u) \leq \exp \left[2 C_{3} \sqrt{\varepsilon}\right]\left(1+C_{3} \sqrt{\varepsilon}\right)=1+\mathcal{O}(\sqrt{\varepsilon})$, as desired. The corresponding $A_{1}$ bound for $v=\exp [G /(p-1)]$ follows similarly from (29). The proof of the theorem is now complete.

[^4]Proof of Lemma 3. We use the averaging procedure of 4 to move from the dyadic version of the theorem (Lemma (1) to the general, local version (Lemma 3). Fix $N$ and assume, without loss of generality, that $f_{S_{N}}=0$. Set $Q_{0}=S_{N+1}$ and $\lambda=2^{n}\|f\|_{*}$. For each $\alpha \in S_{N}$, apply Lemma 1 on $Q_{0}$ to the translate $T_{\alpha} f$ of $f$, where $T_{\alpha} f(x)=f(x-\alpha)$; note that condition (5) holds uniformly for $e^{T_{\alpha} f}$ (in place of $w=e^{f}$ ) as $\alpha$ varies, due to the assumption that $A_{p}\left(e^{f}\right)=1+\varepsilon$. The result is

$$
T_{\alpha} f(x)-\left(T_{\alpha} f\right)_{S_{N+1}}=g^{(\alpha)}(x)+F^{(\alpha)}(x)-G^{(\alpha)}(x)
$$

where $g^{(\alpha)}, F^{(\alpha)}$, and $G^{(\alpha)}$ satisfy (7), (8), and (9), respectively 11 Next, for a.e. $x$ within the cube $S_{N}$, we know that

$$
\begin{aligned}
f(x) & =\frac{1}{\left|S_{N}\right|} \int_{S_{N}} T_{-\alpha}\left(T_{\alpha} f\right)(x) d \alpha \\
& =\frac{1}{\left|S_{N}\right|} \int_{S_{N}} T_{-\alpha}\left(g^{(\alpha)}+\left(T_{\alpha} f\right)_{S_{N+1}}+F^{(\alpha)}-G^{(\alpha)}\right)(x) d \alpha \\
& =g_{N}(x)+F_{N}(x)-G_{N}(x)
\end{aligned}
$$

where, in the last line, $g_{N}(x)=\left|S_{N}\right|^{-1} \int_{S_{N}} T_{-\alpha}\left(g^{(\alpha)}+\left(T_{\alpha} f\right)_{S_{N+1}}\right)(x) d \alpha$ and $F_{N}(x)=\left|S_{N}\right|^{-1} \int_{S_{N}} T_{-\alpha}\left(F^{(\alpha)}\right)(x) d \alpha$, and where $G_{N}$ is defined analogously to $F_{N}$. Now, since $f$ is in BMO, then

$$
\left|\left(T_{\alpha} f\right)_{S_{N+1}}\right| \leq\left|\left(T_{\alpha} f\right)_{S_{N+1}}-f_{S_{N+1}}\right|+\left|f_{S_{N+1}}-f_{S_{N}}\right|+\left|f_{S_{N}}\right| \leq c_{n} \sqrt{\varepsilon}
$$

as follows from (10) and the assumption $f_{S_{N}}=0.12$ The uniform boundedness of $g^{(\alpha)}$ in (77) then insures that $\left|g_{N}\right| \leq C_{3} \sqrt{\varepsilon}$ a.e. on $S_{N}$. In addition, the expansion (20) guarantees that there are non-negative coefficient functions $a_{k}^{(\alpha)}$, depending measurably on $\alpha{ }^{13}$ such that

$$
F^{(\alpha)}(x)=\sum_{Q_{k} \in \mathcal{D}\left(S_{N+1}\right)} a_{k}^{(\alpha)} \chi_{Q_{k}}(x)
$$

Note that this sum runs over $\mathcal{D}\left(S_{N+1}\right)$, a fixed, countable collection of cubes which is indexed by $k$ and independent of $\alpha$; as in $\S 2$, each coefficient $a_{k}^{(\alpha)}$ is either 0 or a number between $\lambda$ and $2 \lambda$. Condition (21) leads to a similar representation for $G^{(\alpha)}$.

It remains to show that $F_{N}$ satisfies the desired $A_{1}$ estimate on $S_{N}$. Fix an arbitrary cube $Q$ within $S_{N}$. Our goal is to show (28), i.e.,

$$
\begin{equation*}
\frac{1}{|Q|} \int_{Q} e^{F_{N}} \leq\left(1+C_{3} \sqrt{\varepsilon}\right) \inf _{Q} e^{F_{N}} \tag{37}
\end{equation*}
$$

[^5]To reach this we will make a number of reductions. First, on the cube $Q$, write $F^{(\alpha)}=F_{1}^{(\alpha)}+F_{2}^{(\alpha)}$, with

$$
F_{1}^{(\alpha)}=\sum_{\ell\left(Q_{k}\right) \geq \ell(Q)} a_{k}^{(\alpha)} \chi_{Q_{k}}, \quad F_{2}^{(\alpha)}=\sum_{\ell\left(Q_{k}\right)<\ell(Q)} a_{k}^{(\alpha)} \chi_{Q_{k}},
$$

where $\ell(Q)$ denotes the side-length of $Q$. Note that only finitely many terms enter into the first sum. Next, define the averaged forms

$$
F_{N, 1}(x)=\frac{1}{\left|S_{N}\right|} \int_{S_{N}} F_{1}^{(\alpha)}(x+\alpha) d \alpha, \quad F_{N, 2}(x)=\frac{1}{\left|S_{N}\right|} \int_{S_{N}} F_{2}^{(\alpha)}(x+\alpha) d \alpha
$$

thus, $F_{N}=F_{N, 1}+F_{N, 2}$. On account of Lemma 1, to prove (37) it suffices to show the two bounds

$$
\begin{equation*}
\sup _{Q} F_{N, 1}-\inf _{Q} F_{N, 1} \leq C \lambda \tag{38}
\end{equation*}
$$

and

$$
\begin{equation*}
\frac{1}{|Q|} \int_{Q} e^{F_{N, 2}} \leq(1+C \lambda) \inf _{Q} e^{F_{N, 2}} \tag{39}
\end{equation*}
$$

where $\lambda=2^{n}\|f\|_{*}$.
Now, (38) is a consequence of the following Lipschitz estimate 14 on the contribution to $F_{N}$ of the terms arising from cubes of a fixed size:

Lemma 4. Let

$$
\hat{F}_{j}(x)=\frac{1}{\left|S_{N}\right|} \int_{S_{N}} \sum_{\ell\left(Q_{k}\right)=2^{-j} \ell\left(S_{N}\right)} a_{k}^{(\alpha)} \chi_{Q_{k}}(x)
$$

so that $F_{N}(x)=\sum_{j=0}^{\infty} \hat{F}_{j}(x)$. If $\sup _{1 \leq i \leq n}\left|x_{i}-y_{i}\right| \leq 2^{-j} \ell\left(S_{N}\right)$, then

$$
\left|\hat{F}_{j}(x)-\hat{F}_{j}(y)\right| \leq \frac{C_{4} 2^{j}\|f\|_{*}}{\ell\left(S_{N}\right)}|x-y|
$$

with $C_{4}$ dependent only on the dimension $n$ (and, in particular, not on $j$ ).
In fact, if $x, y \in Q$ and $r$ is the integer satisfying $2^{-r-1} \ell\left(S_{N}\right)<\ell(Q) \leq 2^{-r} \ell\left(S_{N}\right)$, then $\sup _{1 \leq i \leq n}\left|x_{i}-y_{i}\right| \leq 2^{-r} \ell\left(S_{N}\right)$. Hence

$$
\begin{equation*}
\left|F_{N, 1}(x)-F_{N, 1}(y)\right| \leq \sum_{j=0}^{r}\left|\hat{F}_{j}(x)-\hat{F}_{j}(y)\right| \leq C_{4}\|f\|_{*} \sum_{j=0}^{r} 2^{j} \frac{|x-y|}{\ell\left(S_{N}\right)} \tag{40}
\end{equation*}
$$

The latter sum is no more than $2 \sqrt{n}$, so that (38) holds.
What about (39)? We can, in fact, further simplify the right-hand side there by noting that $F_{N, 2} \geq 0$. As for the left-hand side, from Jensen's inequality and Fubini's theorem it follows that

$$
\begin{aligned}
\frac{1}{|Q|} \int_{Q} e^{F_{N, 2}} & =\frac{1}{|Q|} \int_{Q} \exp \left[\frac{1}{\left|S_{N}\right|} \int_{S_{N}} T_{-\alpha}\left(F_{2}^{(\alpha)}\right)(x) d \alpha\right] d x \\
& \leq \frac{1}{|Q|\left|S_{N}\right|} \int_{Q} \int_{S_{N}} \exp \left[T_{-\alpha}\left(F_{2}^{(\alpha)}\right)(x)\right] d \alpha d x \\
& =\frac{1}{\left|S_{N}\right|} \int_{S_{N}} \frac{1}{|Q|} \int_{Q+\alpha} \exp \left(F_{2}^{(\alpha)}\right)(y) d y d \alpha
\end{aligned}
$$

[^6]For the proof of (37), it thus suffices to obtain a suitable estimate on the inner integral in the last line, i.e., to show that

$$
\begin{equation*}
\frac{1}{|Q|} \int_{Q+\alpha} \exp \left(F_{2}^{(\alpha)}\right)(y) d y=1+\mathcal{O}(\lambda) \tag{41}
\end{equation*}
$$

uniformly for all $\alpha \in S_{N}$. The last integral average can be written, as in (24), in the form

$$
1+\frac{\lambda}{|Q|} \int_{0}^{\infty}\left|E_{\tau, 2}^{(\alpha)}\right| e^{\lambda \tau} d \tau
$$

where

$$
E_{\tau, 2}^{(\alpha)}=\left\{y \in Q+\alpha: F_{2}^{(\alpha)}(y)>\lambda \tau\right\}
$$

But $Q+\alpha$ is contained within a union of $2^{n}$ dyadic subcubes of $S_{N+1}$, each having side-length less than twice that of $Q$. Applying the construction in $\sqrt{2}$ to each of these subcubes and summing leads to the estimate $\left|E_{\tau, 2}^{(\alpha)}\right| \leq c_{n} 2^{-n k}$, when $2(k-1) \leq \tau$. The bound (41) then follows from writing $\int_{0}^{\infty}(\cdots) d \tau$ as the sum $\sum_{k=1}^{\infty} \int_{2(k-1)}^{2 k}(\cdots) d \tau$. The proof of estimate (29) for $G_{N}$ is similar. This settles the last remaining step in the proof of the lemma, and the factorization theorem is thus complete.

## 4. Sharpness of the asymptotic estimate

That the square root is the sharp power in the theorem follows from considering a step function $w$ with the value $1+\sqrt{\varepsilon}$ on one side and $1-\sqrt{\varepsilon}$ on the other side of a hyperplane in $\mathbb{R}^{n}$. This weight satisfies $A_{p}(w)=1+\mathcal{O}(\varepsilon)$, although, as we shall presently show, regardless of how it is factored into a quotient of $A_{1}$ weights, at least one of its factors must have an $A_{1}$ bound exceeding $1+\mathcal{O}(\sqrt{\varepsilon})$.

Proposition. Let $w$ be the step function taking the value $1+\sqrt{\varepsilon}$ in $\mathbb{R}_{+}^{n}$ and $1-\sqrt{\varepsilon}$ in $\mathbb{R}_{-}^{n}$. Suppose that $w=u v^{1-p}$ for $A_{1}$ weights $u$ and $v$. Then

$$
A_{p}(w) \leq 1+c \varepsilon
$$

although

$$
\max \left[A_{1}(u), A_{1}(v)\right] \geq 1+c^{-1} \sqrt{\varepsilon}
$$

The constant $c$ depends only on the index $p$.
Proof. For simplicity, we first show this in the case $p=2$. Divide the unit cube $Q=[-1 / 2,1 / 2]^{n}$ in half, with $I=Q \cap \mathbb{R}_{+}^{n}$ and $J=Q \cap \mathbb{R}_{-}^{n}$. A calculation shows that the $A_{2}$ bound of the given weight $w$ is achieved when the averages of $w$ and $w^{-1}$ are formed symmetrically over $Q$, in which case

$$
A_{2}(w)=\left[\frac{1+\sqrt{\varepsilon}}{2}+\frac{1-\sqrt{\varepsilon}}{2}\right]\left[\frac{1}{2(1+\sqrt{\varepsilon})}+\frac{1}{2(1-\sqrt{\varepsilon})}\right]=\frac{1}{1-\varepsilon}=1+\mathcal{O}(\varepsilon)
$$

Suppose that $w=u / v$ for the pair of $A_{1}$ weights $u$, $v$. If $A_{1}(u) \leq 1+\sqrt{\varepsilon} / 4$, then

$$
\int_{Q} v \geq\left[\frac{1}{1+\sqrt{\varepsilon}}+\frac{1}{1-\sqrt{\varepsilon}}\right] \min \left[\int_{I} u, \int_{J} u\right] \geq \frac{2}{1-\varepsilon} \frac{1}{1+\sqrt{\varepsilon} / 2} \int_{I} u
$$

where the last step is a simple consequence of the assumed $A_{1}$ bound on $u \sqrt{15}$ In addition,

$$
\inf _{Q} v \leq \inf _{I} v=\frac{1}{1+\sqrt{\varepsilon}} \inf _{I} u \leq \frac{2}{1+\sqrt{\varepsilon}} \int_{I} u
$$

Hence

$$
A_{1}(v) \geq \frac{\int_{Q} v}{\inf _{Q} v} \geq \frac{1+\sqrt{\varepsilon}}{(1-\varepsilon)(1+\sqrt{\varepsilon} / 2)} \geq \frac{1}{1-\sqrt{\varepsilon} / 2} \geq 1+\frac{1}{2} \sqrt{\varepsilon}
$$

When $p>2$, the argument is similar: if $A_{1}(u) \leq 1+\sqrt{\varepsilon} / 4$ and $v^{p-1}=u / w$, then the above estimates show that $A_{1}(v) \geq(1+\sqrt{\varepsilon} / 2)^{1 /(p-1)} \geq 1+\sqrt{\varepsilon} / 2$. When $p<2$, it is easier to begin with an $A_{1}$ weight $v$ and to set $u=w v^{p-1}$. In this case, if $A_{1}(v) \leq 1+\sqrt{\varepsilon} / C_{p}$, then $A_{1}(u) \geq(1+\sqrt{\varepsilon})^{-1}\left(1+2 \sqrt{\varepsilon} / C_{p}\right)^{1-p}$; the last quantity exceeds $1+c^{-1} \sqrt{\varepsilon}$, provided that $C_{p}$ is sufficiently large. This completes the proof of the proposition.

[^7]
[^0]:    Received by the editors February 3, 1999.
    1991 Mathematics Subject Classification. Primary 42B25; Secondary 26D15, 46E30.
    Key words and phrases. Jones' factorization theorem, bounded mean oscillation, vanishing mean oscillation, $A_{p}$ condition.
    ${ }^{1}$ In general, all pointwise statements in this paper should be understood to hold only almost everywhere with respect to Lebesgue measure.

[^1]:    ${ }^{2}$ Recall that $M f\left(x_{0}\right)=\sup _{Q}(1 /|Q|) \int_{Q}|f|$, where the supremum runs over all cubes $Q$ containing $x_{0}$. For the fundamental proof that $M$ is bounded on the weighted space $L^{2}(w d x)$ exactly when $w \in A_{2}$, see 1] or 10.
    ${ }^{3}$ Simply observe that for $f$ positive, both $M\left(w^{1 / 2} f\right) \geq w^{1 / 2} f$ and $M\left(w^{-1 / 2} f\right) \geq w^{-1 / 2} f$, so that $S(f) \geq 2 f$. More significantly, the norm of each of the two terms in $S$, viewed as an operator on $L^{2}(d x)$, is strictly greater than 1 .

[^2]:    ${ }^{4}$ The argument follows [6] and [4] closely, with modifications introduced to get around the fact that the proof for the dyadic model case in [4] pp. 360-361] only leads to $A_{1}$ factors with bounds which are at least 2 , even when the $A_{p}$ bound of the weight to be factored is nearly 1 .
    ${ }^{5}$ Note that the intersection $\bigcap_{m} \Omega^{m}$ is a set of measure zero within $Q_{0}$, on account of (15). So it suffices to verify the bound for $g$ on $\Omega^{m} \backslash \Omega^{m+1}$ separately for each non-negative $m$, and this follows from (16).

[^3]:    ${ }^{6}$ Unlike in (12), the sign of the difference is important here.
    ${ }^{7}$ That is, $\widetilde{Q}=\bigcap\left\{Q_{j} \in \mathcal{G}: Q \subset Q_{j}\right\}$. This is consistent with the earlier notation, in which $Q \in \mathcal{G}^{m+1}$ and $\widetilde{Q} \in \mathcal{G}^{m}$.

[^4]:    ${ }^{8}$ The John-Nirenberg inequality has been invoked to move from uniform boundedness in $L^{1}$ to that in $L^{2}$; otherwise, weak compactness would have only guaranteed the existence of a subsequence converging to a measure.
    ${ }^{9}$ See Theorem 3.13 in [14] or Theorem V.1.2 in [16]; in the latter work, this result is attributed to S. Mazur.
    ${ }^{10}$ Suppose that $\left\{\varphi_{J}\right\}$ is a sequence of non-negative, measurable functions that converges a.e. to $\varphi$. What is needed here are both the (standard) $L^{1}$ form of Fatou's lemma, $\int \varphi \leq \lim \inf _{J} \int \varphi_{J}$, as well as its $L^{\infty}$ form: $\lim \inf _{J}\left(\inf \varphi_{J}\right) \leq \inf \varphi ;$ the latter can be verified via a simple proof by contradiction. Recall that we write $\inf \varphi$ for $\operatorname{ess} \inf \varphi$, as indicated in the introduction.

[^5]:    ${ }^{11}$ Symbols such as $\mathcal{G}^{m,(\alpha)}, \mathcal{G}^{(\alpha)}$, and $\Omega^{m,(\alpha)}$ will likewise denote the sets within $Q_{0}$ obtained when $f$ is replaced by its translate $T_{\alpha} f$ in the definitions of $\mathcal{G}^{m}, \mathcal{G}$, and $\Omega^{m}$ in
    ${ }^{12}$ Compare the bound obtained from 34.
    ${ }^{13}$ Choose a dyadic subcube $Q_{k}$ of $Q_{0}$, with $\left|Q_{k}\right|=2^{-n}\left|Q_{0}\right|$. By definition, the coefficient $a_{k}^{(\alpha)}$ satisfies $a_{k}^{(\alpha)}=\left[\left(T_{\alpha} f\right)_{Q_{k}}-\left(T_{\alpha} f\right)_{Q_{0}}\right] \chi_{E_{k}}$, where $E_{k}=\left\{\alpha \in S_{N}:\left[\left(T_{\alpha} f\right)_{Q_{k}}-\left(T_{\alpha} f\right)_{Q_{0}}\right]>\lambda\right\}$. Since $f \in L^{1}\left(S_{N+2}\right)$, then $[\cdots]$ is a continuous function of $\alpha$, and $E_{k}$ is consequently an open set within $S_{N}$. This proves the measurability in $\alpha$ of the coefficient functions $a_{k}^{(\alpha)}$ associated to each first-generation subcube $Q_{k}$ of $Q_{0}$. The argument for cubes of a later generation within $\mathcal{D}\left(Q_{0}\right)$ is analogous.

[^6]:    ${ }^{14}$ This is Lemma 3.2 in (4).

[^7]:    ${ }^{15}$ When $|Q|^{-1} \int_{Q} u=(1+\delta) \inf _{Q} u$ and $Q$ is divided into two halves $I, J$ of equal measure, then a simple calculation shows that $\left(\int_{I} u\right) /\left(\int_{J} u\right) \leq 1+2 \delta$ (see, e.g., 9] §2, Cor. 7]).
