CODING INTO K BY REASONABLE FORCING

RALF-DIETER SCHINDLER

ABSTRACT. We present a technique for coding sets “into K ,” where K is the core model below a strong cardinal. Specifically, we show that if there is no inner model with a strong cardinal then any $X \subset \omega_1$ can be made Δ^1_3 (in the codes) in a reasonable and stationary preserving set generic extension.

1. INTRODUCTION

The present paper was inspired by a talk Itay Neeman gave on his joint work [5] and [6] with J. Zapletal. Starting from a large cardinal dose somewhat above $AD^{L(\mathbb{R})}$ (the assertion that $L(\mathbb{R})$ is a model of the Axiom of Determinacy) they show that no set of ordinals not already in $L(\mathbb{R})$ can be coded into $L(\mathbb{R})$ by a set-sized reasonable forcing, and moreover that the theory of $L(\mathbb{R})$ with parameters for ordinals and reals from V is frozen with respect to all generic extensions by set-sized reasonable forcings. “Reasonability” was introduced by Foreman and Magidor in [2]. A notion of forcing P is called *reasonable* if for any $\alpha \geq \omega_1$ it is true that $[\alpha]^\omega \cap V$ is stationary in $[\alpha]^\omega \cap V[G]$, for every G that is P -generic over V (cf. [2], Definition 3.1). This weakens Shelah’s concept of “properness.” Recall that P is called *proper* if for any $\alpha \geq \omega_1$ and any stationary $S \subset [\alpha]^\omega \cap V$ it is true that S remains stationary in $[\alpha]^\omega \cap V[G]$, for every G that is P -generic over V (cf. [8]).

On the other hand, Woodin (unpublished) has shown that if the theory of $L(\mathbb{R})$ with real parameters from V is frozen with respect to all set generic extensions whatsoever and symmetric submodels thereof, then in fact $AD^{L(\mathbb{R})}$ holds. (A version of this was rediscovered independently by Steel; cf. [11].) There is no denying the fact that a remarkable theorem of this sort provides one more bit of evidence for the naturalness (if not truth in $L(\mathbb{R})$) of AD , the Axiom of Determinacy.

Now in the light of [5] and [6] one obvious question is: can Woodin’s result be strengthened by restricting the forcings to reasonable ones? This is non-trivial, as Woodin’s proof uses the forcing for collapsing a singular cardinal to become countable, which is anything but reasonable. More specifically:

Question 1. Suppose that for every formula $\Phi(v)$, for every real $r \in \mathbb{R}^V$, for every G that is P -generic, where $P \in V$ is reasonable, and for every symmetric submodel

Key words and phrases. Set theory, descriptive set theory, proper forcing, large cardinals.

The author would like to thank Itay Neeman, Philip Welch, and Sy Friedman for their interest and for their many hints and comments. John Steel even provided a crucial subclaim, and again I do say thanks for his intellectual support during my stay in Berkeley. I gratefully acknowledge financial support from the Deutsche Forschungsgemeinschaft (DFG).

V^* of $V[G]$,

$$L(\mathbb{R}^V) \models \Phi(r) \text{ iff } L(\mathbb{R}^{V^*}) \models \Phi(r).$$

Does $AD^{L(\mathbb{R})}$ hold (in every set generic extension)?

We conjecture but cannot prove that the answer to this question is “yes.” In this paper, we can only give partial evidence in favor of this conjecture. In fact, the argument given below can easily be transformed to show that under its assumption global Π_1^1 -determinacy holds.

If in particular ω_1 is not to be collapsed, any attempt to answer this question in the affirmative seems to essentially have to use some coding techniques. As the coding is supposed to be set-sized, one cannot use Jensen coding as in [1] (although it is reasonable). A set-sized variant of it (as in [9], say) only works below $\aleph_1^\sharp$ (or if V is not closed under sharps, for that matter). In general, “coding into K ” techniques are called for, where K is the core model, and this is what makes the problem really interesting (and difficult, once we get higher up in the large cardinal zoo).

So the above question naturally leads to the following:

Question 2. Suppose that $AD^{L(\mathbb{R})}$ does not hold. Let $X \subset \omega_1$. Can X be coded into $L(\mathbb{R})$ by a set-sized reasonable forcing?

This would be a dual fact to the Anti-Coding Theorem of [5] and [6]. However, the transit via inner model theory for attacking this latter question is blocked at the time of writing by some pretty technical obstacles.

Let us now state the main results of the present paper.

Theorem 1.1. *Suppose that there is no inner model with a strong cardinal. Let $X \subset \omega_1$. Then X is Δ_3^1 (in the codes) in a generic extension by a set-sized reasonable forcing.*

Theorem 1.2. *Suppose that there is no inner model with a strong cardinal. Then there is a generic extension by a set-sized reasonable forcing with a Δ_3^1 -well-ordering of its reals.*

Theorem 1.3. *Suppose that for every Σ_4^1 -formula $\Phi(v)$, for every G_1 that is P_1 -generic over V , where $P_1 \in V$ is reasonable, for every real $r \in \mathbb{R}^{V[G_1]}$, and for every further G_2 that is P_2 -generic over $V[G_1]$, where $P_2 \in V[G_1]$ is reasonable,*

$$V[G_1] \models \Phi(r) \text{ iff } V[G_1][G_2] \models \Phi(r).$$

Then there is an inner model with a strong cardinal.

By the following result of Woodin (unpublished), 1.3 is best possible in the sense that one cannot derive more large-cardinal strength from its assumption. Let κ be a strong cardinal, let $\lambda = 2^{2^\kappa}$, and let G be $Col(\lambda, \omega)$ -generic over V . Then any set generic extension $V[G][H_1]$ of $V[G]$ is Σ_4^1 -correct in any of its set generic extensions, $V[G][H_1][H_2]$. As 1.3 will be an immediate corollary to 1.2, 1.2 itself is best possible in the sense that its anti-large cardinal assumption cannot be weakened.

Also, suppose V to be the minimal inner model with one strong cardinal, say $V \models “\kappa$ is strong,” and let G be $Col(\kappa^{++}, \omega)$ -generic over V . By Woodin’s result, $V[G]$ is Σ_4^1 -correct in its set generic extensions. Writing $\omega_1 = \omega_1^{V[G]}$, we have that $\mathcal{J}_{\omega_1}^V$ cannot be Σ_3^1 in the codes: otherwise the Π_4^1 -statement

$$\forall \text{ countable } \xi \exists \text{ countable } \alpha > \xi \quad \rho_\omega(\mathcal{J}_\alpha^V) \leq \kappa^{++}$$

would be true in $V[G]$, but could be made false by collapsing ω_1 , contradicting Σ_4^1 -correctness. This implies that 1.1 is best possible, again in the sense that its anti-large-cardinal assumption cannot be weakened.

In subsequent work, [7], the present author has shown that neither in the statement of 1.1, nor of 1.2, nor of 1.3, can “remarkable” be replaced by “proper.” (Cf. the discussion after the proof of Claim 3’.)

2. CODING BELOW ONE STRONG CARDINAL

Instead of directly aiming at proving 1.1, 1.2, and 1.3, we shall first present a reasonable generic extension of V under the assumption that there is no inner model with a strong cardinal. This extension will be called V_4 below, and it will be the case that in V_4 there is a real a such that $H_{\omega_2} = J_{\omega_2}^{K(a)}$. (Here, H_{ω_2} is the set of all sets hereditarily smaller than $\aleph_2$, and $K(a)$ is the core model built over a , cf. the second next paragraph.) We shall then see that this construction in fact easily gives rise to proofs of 1.1, 1.2, and 1.3.

So let us assume throughout this section that there is no inner model with a strong cardinal. Then K , the core model below a strong cardinal, exists (cf. [4]; we here have to assume just a little familiarity with K). Moreover, K is also the core model in the sense of all set generic extensions. We shall code an initial segment of V “into K .” The heart of the matter will be the task of checking that a certain “ K -reshaping” is ω -distributive.

For this in turn it is convenient (although not necessary) at some point during the construction to switch from $K[A]$ to $K(A)$ for a set A of ordinals, a distinction which should be explicitly explained. Fix A , a set of ordinals. Let E code K ’s extender sequence, i.e., $K = L[E]$. Then by $K[A]$ we mean $L[E, A]$, i.e., the constructible universe built with the two additional predicates $v \in E$ and $v \in A$ at hand. Hence $K[A]$ is just the least inner model W with $K \cup \{A\} \subset W$. We shall also write $K_\kappa[A]$ for $J_\kappa[E, A]$, for an ordinal κ . Notice that the presence of A in $K[A]$ in general destroys the internal structure of K . On the other hand, by $K(A)$ we mean the core model built *over* A ; i.e., starting from $TC(\{A\})$, the transitive closure of $\{A\}$, we run the recursive construction of K , with “strong A -mice” instead of “strong mice” (cf. [4] on the recursive definition of K ; to give a reference for $K(A)$, cf. [10]; p. 59). By our assumption that there is no inner model with a strong cardinal, $K(A)$ exists, and in contrast to $K[A]$ it has a fine structure and can be iterated “above A .”

With these things in mind, we may now commence with our construction.

To get things started, we use almost disjoint forcing in its simplest form. Fix δ , a singular cardinal of uncountable cofinality and such that $\delta^{\aleph_0} = \delta$ (for example, let δ be a strong limit). We also may and shall assume that δ is a cutpoint of K ; i.e., if $E_\alpha \neq \emptyset$ is an extender from K ’s extender sequence with $\alpha \geq \delta$, then in fact the critical point of E_α is $\geq \delta$, too. (Here we use that there is no inner model with a strong cardinal. If there were no such δ then using Fodor we would get a strong cardinal in K .)

By [4], we know that $\delta^{+K} = \delta^+$. We may also assume without loss of generality that $2^\delta = \delta^+$, because otherwise we may collapse 2^δ onto δ^+ by a δ -closed preliminary forcing. We may hence pick $A \subset \delta^+$ with the property that $H_{\delta^+} = L_{\delta^+}[A]$.

Now let G_1 be $Col(\delta, \omega_1)$ -generic over V . Notice that the forcing is ω -closed. Set $V_1 = V[G_1]$. We have that $\omega_2^{V_1} = \delta^+ = \delta^{+K}$. Let $B \subset \omega_1$ code G_1 (in the sense that $G_1 \in L_{\omega_2^{V_1}}[B]$).

Claim 1. In V_1 , $H_{\omega_2} = L_{\omega_2}[A, B]$.

Proof. Easy, using the fact that $Col(\delta, \omega_1)$ is δ^+ -c.c. We shall have to repeat the argument a couple of times, so we'll be more explicit next time. $\square$ (Claim 1)

In what follows we let ω_2 denote $\omega_2^{V_1}$. It will also be the ω_2 of all further extensions.

Now in K we may pick $(A'_\xi : \xi < \delta^+)$, a sequence of almost disjoint subsets of δ . In $L_{\omega_2}[B]$ we may pick a bijective $g: \omega_1 \rightarrow \delta$. Then, if we let $\alpha \in A_\xi$ iff $g(\alpha) \in A'_\xi$ for $\alpha < \omega_1$ and $\xi < \delta^+$, we have that $(A_\xi : \xi < \delta^+)$ is a sequence of almost disjoint subsets of ω_1 .

In V_1 , we may pick $A_1 \subset \omega_2$ with $H_{\omega_2} = L_{\omega_2}[A, B] = L_{\omega_2}[A_1]$ (for example, let $A_1 = A \oplus B$, the “join” of A and B). We let P_2 be the forcing for coding A_1 by a subset of ω_1 , using the almost disjoint sets A_ξ .

To be specific, P_2 consists of pairs $p = (l(p), r(p))$, where $l(p): \alpha \rightarrow 2$ for some $\alpha < \omega_1$ and $r(p)$ is a countable subset of ω_2 . We have $p = (l(p), r(p)) \leq_{P_2} q = (l(q), r(q))$ iff $l(p) \supset l(q)$, $r(p) \supset r(q)$, and for all $\xi \in r(q)$, if $\xi \in A_1$ then

$$\{\beta \in \text{dom}(l(p)) \setminus \text{dom}(l(q)) : l(p)(\beta) = 1\} \cap A_\xi = \emptyset.$$

By a Δ -system argument, P_2 has the ω_2 -c.c. It is clearly ω -closed, so no cardinals are collapsed. Moreover, if G_2 is P_2 -generic over V_1 , and if we set

$$C' = \bigcup_{p \in G_2} \{\beta \in \text{dom}(l(p)) : l(p)(\beta) = 1\},$$

then $C' \subset \omega_1$, and we have that, for all $\xi < \omega_2$,

$$\xi \in A_1 \text{ iff } \text{Card}(C' \cap A_\xi) \leq \aleph_0.$$

This means that A_1 is an element of any inner model containing $(A_\xi : \xi < \omega_2)$ and C' . (Of course, much more holds.) Letting $C = B \oplus C'$, an example of such a model is $K[C]$ in the sense explained above. Set $V_2 = V_1[G_2]$. We then also have, by the same argument as for Claim 1,

Claim 2. In V_2 , $H_{\omega_2} = K_{\omega_2}[C]$.

Proof. Let X be a bounded subset of ω_2 in V_2 . As P_2 is ω_2 -c.c. and $P_2 \in H_{\omega_2}$, X has a name $\dot{X}$ in $H_{\omega_2}^{V_1} = L_{\omega_2}[A_1]$. That is, there is $\omega_1 < \theta < \omega_2$ such that $\dot{X} \in L_\theta[A_1 \cap \theta]$. Further, there is $\theta < \theta' < \omega_2$ such that $(A_\xi : \xi < \theta) \in K_{\theta'}[B]$, so that $A_1 \cap \theta \in K_{\theta'}[B \oplus C'] = K_{\theta'}[C]$. So $\dot{X} \in K_{\theta'}[C]$, and hence $X \in K_{\omega_2}[C]$ by $C' \in K_{\theta'}[C]$.

We have shown that $H_{\omega_2} \subset K_{\omega_2}[C]$ in V_2 . But $K_{\omega_2}[C] \subset H_{\omega_2}$ is trivial.

$\square$ (Claim 2)

Now let $C_1 \subset \omega_1$ be such that $C \in L_{\omega_2}[C_1]$ as well as $\mathcal{J}_\delta^K \in L_{\omega_2}[C_1]$ (for example, let $C_1 = C \oplus$ a code for $\mathcal{J}_\delta^K$).

Our task is now to code “down to a real,” i.e., we want to find a further (ω -distributive) generic extension in which $H_{\omega_2} \subset K(a)$, where a is a real. As we cannot expect ω_1 to be a successor in K (and as we certainly cannot force this

to be the case using an ω_1 -preserving forcing), we have to use the slightly more advanced coding technique which first requires C_1 to become “reshaped.”

However, there is no hope of showing that reshaping is reasonable if we work with the wrong definition of “being reshaped.” As a matter of fact, the following one works.

Definition 2.1. Let $X \subset \omega_1$. We say that an f is X -reshaping if $f: \alpha \rightarrow 2$ for some $\alpha \leq \omega_1$, and moreover, for all $\beta \leq \alpha$ with $\beta < \omega_1$,

$$K(X \cap \beta, f \upharpoonright \beta) \models \text{Card}(\beta) \leq \aleph_0.$$

The reader will have noticed the round brackets in this definition. This indicates a convenient switch from $K[\cdot \cdot \cdot]$ to $K(\cdot \cdot \cdot)$ in our argument. It is also possible but virtually less elegant to keep going with the square brackets.

Now let P_3 be the forcing for adding a C_1 -reshaping characteristic function on a subset of ω_1 , defined inside V_2 . Formally, $p \in P_3$ iff p is C_1 -reshaping and $\text{dom}(p) < \omega_1$. The order is by reverse inclusion, i.e., $q \leq_{P_3} p$ iff $q \supset p$. (In fact we may assume “w.l.o.g.” that every C_1 -reshaping p has $\text{dom}(p) < \omega_1$, because otherwise we could just fix a counterexample and go ahead with forcing with P_4 .)

It is easy to see that for any $\alpha < \omega_1$, the set $D^\alpha = \{p \in P_3 : \text{dom}(p) \geq \alpha\}$ is open dense in P_3 (this property of P_3 is called its “extendability”). In fact, given $q \in P_3$ with $\text{dom}(q) < \alpha$, we may pick any $p \leq q$ with $\text{dom}(p) = \alpha + \omega$ such that $p \upharpoonright [\text{dom}(q), \text{dom}(q) + \omega]$ codes some bijective $f: \omega \rightarrow \alpha + \omega$; then $p \in D^\alpha$.

Claim 3. P_3 is ω -distributive.

Proof. We first need the following observation, which is due to John Steel. The argument proving it also has to be repeated a couple of times.

Subclaim 1 (Steel). In V_2 , $H_{\omega_2} = J_{\omega_2}^{K(C_1)}$.

Proof. Let $W = K^{K(C_1)}$, the core model built inside $K(C_1)$. In V_2 , let θ be any regular cardinal, and let κ be a singular cardinal with $\text{cf}(\kappa) > \theta$. By weak covering applied inside $K(C_1)$ (cf. [4]), we have that $\text{cf}^{K(C_1)}(\kappa^{+W}) \geq \kappa$, which implies that $\text{cf}^{V_2}(\kappa^{+W}) \geq \text{cf}^{V_2}(\kappa) > \theta$. Hence, inside V_2 , for any regular θ there is a stationary class of cardinals κ with $\text{cf}(\kappa^{+W}) > \theta$.

But this implies that inside V_2 , W is a universal weasel in the sense that the coiteration of W with any (set-sized) mouse terminates after $< OR$ many steps and the mouse-side is always simple.

Moreover, as $\mathcal{J}_\delta^K \in K(C_1)$, an easy absoluteness argument using the recursive definition of K (cf. [4] or [10], p. 85 f.) yields that $\mathcal{J}_\delta^K \triangleleft W$, i.e., $\mathcal{J}_\delta^K$ is an initial segment of W .

By [4], there is a normal iteration of K giving W (cf. also [10], Theorem 8.13). Let $\pi: K \rightarrow W$ be the iteration map. Because δ is a cutpoint in K and $\mathcal{J}_\delta^K \triangleleft W$, we must have $\pi \upharpoonright \delta = \text{id}$. But as $\mathcal{J}_{\delta+\kappa}^K$ is an initial segment of every simple iterate of K above δ , this readily implies that $\mathcal{J}_{\delta+W}^K = \mathcal{J}_{\delta+\kappa}^K$.

Hence $J_{\omega_2}^K \in W \subset K(C_1)$, and in fact $J_{\omega_2}^K \subset J_{\omega_2}^{K(C_1)}$ by acceptability. This easily gives the claim. $\square$ (Subclaim 1)

We remark in passing that Subclaim 1 would not have to hold if δ had not been chosen as a cutpoint of K .

We now fix a condition $p \in P_3$, and open dense sets D_i , $i < \omega$. We have to find $q \leq_{P_3} p$ with $q \in D_i$ for every $i < \omega$. We are working in V_2 . Let us consider the

model

$$\mathfrak{M} = (H_{\omega_2}; \in, C_1, E^{K(C_1)} \upharpoonright \omega_2, (D_i : i < \omega), p),$$

where $E^{K(C_1)}$ is the extender sequence from $K(C_1)$. Let X_0 be the universe of the least Σ_1 submodel of $\mathfrak{M}$, and for $n > 0$ let X_n be the universe of the least Σ_1 submodel of $\mathfrak{M}$ containing $X_{n-1} \cup \{X_{n-1}\}$. Here, “least” refers to some fixed Σ_1 Skolem function for $\mathfrak{M}$ which is definable over $\mathfrak{M}$. Let $X_\omega = \bigcup_{n < \omega} X_n$. Of course, every X_n , $n \leq \omega$, is countable. For $n \leq \omega$, let

$$\pi_n : \mathfrak{N}_n = (\bar{H}_n; \in, C_1 \cap \kappa_n, \bar{E}_n, (\bar{D}_{i,n} : i < \omega), p) \rightarrow_{\Sigma_1} (X_n; \dots) \prec \mathfrak{M}$$

be the inverse of the Mostowski collapse of X_n , where $\kappa_n = c.p.(\pi_n)$ is the critical point of π_n . (Of course, $\pi_n(\kappa_n) = \omega_1$.) Let us write $\pi = \pi_\omega$, $\mathfrak{N} = \mathfrak{N}_\omega$, etc. in what follows. It is crucial to notice that $(\kappa_n : n < \omega)$ is definable over $\mathfrak{N}$, as $\pi^{-1} \restriction X_n$ is the least Σ_1 submodel of $\mathfrak{N}$ (containing $\pi^{-1} \restriction X_{n-1} \cup \{\pi^{-1} \restriction X_{n-1}\}$ for $n > 0$).

Subclaim 2. $\mathfrak{N} \in K(C_1 \cap \kappa)$.

Proof. $\bar{H}$ is the universe of a $(C_1 \cap \kappa)$ -premouse, call it N , with extender sequence $\bar{E}$. Obviously, it suffices to prove that $N \in K(C_1 \cap \kappa)$. N is iterable, as witnessed by $\pi : N \rightarrow_{\Sigma_1} \mathcal{J}_{\omega_2}^{K(C_1)}$. We have that $\rho_1(N) \leq \kappa$, as N is the Σ_1 hull of $\kappa \cup \{(\bar{D}_i : i < \omega), p\}$ taken inside N . Moreover, N is sound: as it does not have any total extenders on its sequence, it can't be a proper iterate of its core.

We coiterate N with $K(C_1 \cap \kappa)$, getting comparable N^* and K^* . Because $\rho_1(N) \leq \kappa$, no non-trivial iterate of N can be sound. This implies that, by the universality of $K(C_1 \cap \kappa)$, N cannot be moved at all in the comparison, i.e., $N^* = N$.

Now suppose that $K(C_1 \cap \kappa)$ were to be moved, i.e., $K^* \neq K(C_1 \cap \kappa)$. Let ν be the index of the first extender of the iteration from $K(C_1 \cap \kappa)$ to K^* . We have that ν is a cardinal in K^* . But then $\nu > N \cap OR$, as $\rho_1(N) \leq \kappa$ and $N \trianglelefteq K^*$. This means that there was no need to iterate $K(C_1 \cap \kappa)$ at all, so that in fact $N \triangleleft K(C_1 \cap \kappa)$. In particular, $N \in K(C_1 \cap \kappa)$. $\square$ (Subclaim 2)

By the remark right before the statement of Subclaim 2 we thus have that

$$K(C_1 \cap \kappa) \models \text{Card}(\kappa) \leq \aleph_0.$$

We are now going to construct a sequence $(p_i : i < \omega)$ of conditions below p such that $p_{i+1} \leq_{P_3} p_i$ and $p_{i+1} \in D_i$ for all $i < \omega$. We also want to maintain inductively that $p_i \in \bar{H}_i$ for all $i < \omega$. To commence, let $p_0 = p$. (Notice that $p_0 \in \bar{H}_0$.) Now suppose that p_i is given, $p_i \in \bar{H}_i$, some $i < \omega$. Then $\text{dom}(p_i) < \kappa_i$, and $p_i \in \bar{H}_{i+1}$, too. Applying the extendability of $\pi_{i+1}^{-1}(P_3)$ and the density of $\bar{D}_{i,i+1}$ inside $\mathfrak{N}_{i+1}$, it is easy to find $p_{i+1} \leq_{P_3} p_i$ such that $p_{i+1} \in \bar{H}_{i+1}$, $p_{i+1} \in \bar{D}_{i,i+1} \subset D_{i,i+1}$, and $\text{dom}(p_{i+1}) \geq \kappa_i$.

Now set $q = \bigcup_{i < \omega} p_i$. We have arranged that $\text{dom}(q) = \bigcup_{i < \omega} \kappa_i = \kappa$. But this implies that q is C_1 -reshaping, because $K(C_1 \cap \kappa, q) \models \text{Card}(\kappa) \leq \aleph_0$. (We even have that $K(C_1 \cap \kappa) \models \text{Card}(\kappa) \leq \aleph_0$.) Thus $q \in P_3$, and q is as desired.

$\square$ (Claim 3)

As a matter of fact, a somewhat more involved variation of the previous argument shows that P_3 is stationary preserving. (Recall that a notion of forcing P is called *stationary preserving* if every stationary $S \subset \omega_1$ remains stationary in any generic extension obtained from forcing with P .)

Claim 3'. Let $S \in \mathcal{P}(\omega_1) \cap V_2$ be stationary in V_2 . Then $P_3 \Vdash \check{S}$ is stationary."

Proof. Let $r \in P_3$ be such that $r \Vdash \dot{C}$ is a club subset of ω_1 ." W.l.o.g., $\dot{C} \in H_{\omega_2}$. Let $p \leq_{P_3} r$, and consider the model

$$\mathfrak{M} = (H_{\omega_2}; \in, C_1, E^{K(C_1)} \upharpoonright \omega_2, \dot{C}, p).$$

Let $C^* \subset \omega_1$ be the set of all $\kappa < \omega_1$ such that if X is the universe of the least Σ_1 submodel of $\mathfrak{M}$ containing κ , then $\kappa = X \cap \omega_1$. Obviously, C^* is club in ω_1 , so that we may pick some $\kappa \in S \cap C^*$. We aim to construct $q \leq_{P_3} p$ with $q \Vdash \check{\kappa} \in \dot{C}$.

Let X witness $\kappa \in C^*$, and let

$$\pi : \mathfrak{N} = (\bar{H}; \in, C_1 \cap \kappa, \bar{E}, \bar{C}, p) \rightarrow_{\Sigma_1} (X; \dots) \prec \mathfrak{M}$$

be the inverse of the Mostowski collapse of X . Unfortunately, we won't have in general that $K(C_1 \cap \kappa) \models \text{Card}(\kappa) \leq \aleph_0$ as in the proof of Claim 3. However, if we let N be defined exactly as there, we shall again have that N is sound, and $\rho_1(N) \leq \kappa$; then $N \triangleleft K(C_1 \cap \kappa)$, and in fact $N \triangleleft \mathcal{J}_{\kappa+K(C_1 \cap \kappa)}^{K(C_1 \cap \kappa)}$. This will enable us to use an argument from [9] to build q .

We may assume w.l.o.g. that $\kappa = \omega_1^{K(C_1 \cap \kappa)}$, as otherwise κ is countable in $K(C_1 \cap \kappa)$ and the argument collapses to the one for Claim 3. As N has size κ in $K(C_1 \cap \kappa)$, we may pick a club $E \subset \kappa$ in $K(C_1 \cap \kappa)$ which grows faster than all clubs in N , i.e., whenever $\bar{E} \subset \kappa$ is a club in N then $E \setminus \bar{E}$ is bounded in κ . Let $(\lambda_i : i < \omega)$ be a sequence of ordinals below κ which is cofinal in κ . Let $D_i = \{s : \text{dom}(s) \geq \lambda_i \wedge \exists \alpha \geq \lambda_i \ s \Vdash \check{\alpha} \in \dot{C}\}$, for $i < \omega$. Then $(D_i : i < \omega) \subset \text{ran}(\pi)$ is a sequence of open dense subsets of P_3 .

We are now going to construct a sequence $(p_i : i < \omega)$ of conditions below p such that $p_{i+1} \leq_{P_3} p_i$ and $p_{i+1} \in D_i$. We also want to maintain inductively that $p_{i+1} \in \bar{H}$. (Notice that $p \in \bar{H}$ to begin with.)

To commence, let $p_0 = p$. Now suppose that p_i is given, $p_i \in N$. Set $\alpha = \text{dom}(p_i) < \kappa$. Work inside N for a minute. For all β such that $\alpha \leq \beta < \kappa$ we may pick some $p^\beta \leq_{P_3} p_i$ such that $p^\beta \in \pi^{-1}(D_i)$, $\text{dom}(p^\beta) > \beta$, and for all limit ordinals λ , $\alpha \leq \lambda \leq \beta$, $p^\beta(\lambda) = 1$ iff $\lambda = \beta$. Then there is $\bar{E}$ club in κ such that for any $\eta \in \bar{E}$, $\beta < \eta \Rightarrow \text{dom}(p^\beta) < \eta$.

Now back in $K(C_1 \cap \kappa)$, we may pick $\beta \in E$ such that $E \setminus \bar{E} \subset \beta$. Set $p_{i+1} = p^\beta$, and for future reference let $\beta = \beta_{i+1}$. Of course $p_{i+1} \in D_i \cap \bar{H}$. We also have that $\text{dom}(p_{i+1}) < \min\{\epsilon \in E : \epsilon > \beta\}$, so that for all limit ordinals $\lambda \in E \cap \text{dom}(p_{i+1}) \setminus \text{dom}(p_i)$ we have that $p_{i+1}(\lambda) = 1$ iff $\lambda = \beta_{i+1}$.

Now set $q = \bigcup_{i < \omega} p_i$. We have arranged that $\text{dom}(q) = \bigcup_{i < \omega} \lambda_i = \kappa$. The only problem left to verify is that q is a condition, because if so then clearly $q \Vdash \check{\kappa} \in \dot{C}$; i.e., we want to see that

$$K(C_1 \cap \kappa, q) \models \text{Card}(\kappa) \leq \aleph_0.$$

But by the construction of the p_i 's we have that

$$\begin{aligned} & \{\lambda \in E \cap (\text{dom}(q) \setminus \text{dom}(p)) : \lambda \text{ is a limit ordinal and } q(\lambda) = 1\} \\ &= \{\beta_{i+1} : i < \omega\}, \end{aligned}$$

which is a cofinal subset of E . It hence suffices to verify that E is an element of $K(C_1 \cap \kappa, q)$, because then $\{\beta_{i+1} : i < \omega\} \in K(C_1 \cap \kappa, q)$ witnesses that $\text{Card}(\kappa) \leq \aleph_0$.

But $E \in K(C_1 \cap \kappa, q)$ is shown by the argument for Subclaim 1: we build $W = K(C_1 \cap \kappa)^{K(C_1 \cap \kappa, q)}$, observe its universality in V_2 , and deduce that $E \in J_{\omega_2}^{K(C_1 \cap \kappa)} = J_{\omega_2}^W \subset K(C_1 \cap \kappa, q)$. $\square$ (Claim 3')

On the other hand, it is shown in [7] that P_3 is not always proper. In fact, if V is obtained from L by Levy collapsing a remarkable cardinal in L (in particular, $0^\sharp$ does not exist and $K = L$), then no $L(\mathbb{R})$ of any proper set forcing extension whatsoever can contain an ω_1 sequence of pairwise distinct reals.

Now let G_3 be P_3 -generic over V_2 , and set $V_3 = V_2[G_3]$. By the extendability of P_3 we have that $\bigcup G_3$ is a C_1 -reshaping function with domain ω_1 . Let C'' be that subset of ω_1 having $\bigcup G_3$ as its characteristic function, and let D code $C_1 \oplus C''$. Again we get:

Claim 4. In V_3 , $H_{\omega_2} = J_{\omega_2}^{K(D)}$.

Proof. The only new point here is that we have to check that $J_{\omega_2}^{K(C_1)} \subset J_{\omega_2}^{K(D)}$. But here we can argue exactly as for Subclaim 1 above, by building $K(C_1)^{K(D)}$, observing its universality, and deducing that $J_{\omega_2}^{K(C_1)} \subset K(D)$. $\square$ (Claim 4)

We may now finally code down to a real by using almost disjoint forcing once more. By the fact that D is “ K -reshaped,” there is a (unique) sequence $(a_\beta : \beta < \omega_1)$ of subsets of ω such that for each $\beta < \omega_1$, a_β is the $K(D \cap \beta)$ -least subset of ω that is almost disjoint from any $a_{\bar{\beta}}$ for $\bar{\beta} < \beta$.

We then let P_4 consist of all pairs $p = (l(p), r(p))$, where $l(p) : n \rightarrow 2$ for some $n < \omega$ and $r(p)$ is a finite subset of ω_1 . We let $p = (l(p), r(p)) \leq_{P_4} q = (l(q), r(q))$ iff $l(p) \supset l(q)$, $r(p) \supset r(q)$, and for all $\beta \in r(q)$, if $\beta \in D$ then

$$\{\gamma \in \text{dom}(r(p)) \setminus \text{dom}(r(q)) : r(p)(\gamma) = 1\} \cap a_\beta = \emptyset.$$

By another Δ -system argument, P_4 has the c.c.c. Moreover, if G_4 is P_4 -generic over V_3 , and if we set

$$a = \bigcup_{p \in G_4} \{\gamma \in \text{dom}(l(p)) : l(p)(\gamma) = 1\},$$

then we have that for $\gamma < \omega_1$,

$$\gamma \in D \text{ iff } \text{Card}(a \cap a_\gamma) < \aleph_0.$$

We finally get

Claim 5. In V_4 , $H_{\omega_2} = J_{\omega_2}^{K(a)}$.

Proof. In order to show that $J_{\omega_2}^{K(D)} \subset K(a)$ we first have to verify $D \in K(a)$. This is easily seen to follow (combined with the uniform definability of the a_β 's) from the fact that if $D \cap \gamma \in K(a)$ then $J_{\omega_2}^{K(D \cap \gamma)} \subset K(a)$ (which in turn is true by the argument for Subclaim 1).

But then one more Subclaim 1 type argument proves $J_{\omega_2}^{K(D)} \subset K(a)$.

$\square$ (Claim 5)

At last, we observe that the 4-step iteration yielding from V to V_4 is reasonable. Let α be any uncountable ordinal. Because P_1 , P_2 , and P_3 are all ω -distributive, we have that $[\alpha]^\omega \cap V = [\alpha]^\omega \cap V_3$. But P_4 is c.c.c., hence proper, which implies that $[\alpha]^\omega \cap V$ is stationary in $[\alpha]^\omega \cap V_4$.

Actually, we also get that every $S \in \mathcal{P}(\omega_1) \cap V$ which is stationary in V remains stationary in V_4 . Clearly, any such S is still stationary in V_2 , as P_1 and P_2 are both ω -closed, hence proper. But then S is stationary in V_3 by Claim 3', and so in the end S is still stationary in V_4 by the properness of P_4 . In other words, the 4-step iteration from V to V_4 is also stationary preserving.

3. GETTING THE THEOREMS

We may now easily derive 1.1, 1.2, and 1.3 from the work done in the previous section.

Proof of 1.1. Let us assume that there is no inner model with a strong cardinal. Fix $X \subset \omega_1$. Running the construction of the last section, we may certainly assume w.l.o.g. that for all $\xi < \omega_1$, $\xi \in X$ iff $2\xi \in D$. But then we have that in V_4 , $\xi \in X$ iff

$$\begin{aligned} \exists(a_\gamma: \gamma \leq 2\xi) \exists d \subset 2\xi + 1 [\forall \gamma \leq 2\xi (a_\gamma \text{ is the } K(d \cap \gamma)\text{-least} \\ \text{subset of } \omega \text{ a.d. from all } a_{\bar{\gamma}}, \bar{\gamma} < \gamma, \\ \text{and } \gamma \in d \leftrightarrow \text{Card}(a \cap a_\gamma) < \aleph_0) \text{ and } 2\xi \in d]. \end{aligned}$$

But a_γ is the $K(d \cap \gamma)$ -least subset of ω a.d. from all $a_{\bar{\gamma}}, \bar{\gamma} < \gamma$, iff a_γ is the $\mathcal{M}$ -least subset of ω a.d. from all $a_{\bar{\gamma}}, \bar{\gamma} < \gamma$, for all $(d \cap \gamma)$ -mice $\mathcal{M}$ with $\{a_{\bar{\gamma}}: \bar{\gamma} \leq \gamma\} \subset \mathcal{M}$. We may hence rewrite the displayed formula as

$$\begin{aligned} \exists(a_\gamma: \gamma \leq 2\xi) \exists d \subset 2\xi + 1 \exists(\mathcal{M}_\gamma: \gamma \leq 2\xi) [\forall \gamma \leq 2\xi (\mathcal{M}_\gamma \text{ is a} \\ (d \cap \gamma)\text{-mouse with } \{a_{\bar{\gamma}}: \bar{\gamma} \leq \gamma\} \subset \mathcal{M}_\gamma, \\ a_\gamma \text{ is the } \mathcal{M}_\gamma\text{-least subset of } \omega \text{ a.d. from all } a_{\bar{\gamma}}, \bar{\gamma} < \gamma, \\ \text{and } \gamma \in d \leftrightarrow \text{Card}(a \cap a_\gamma) < \aleph_0) \text{ and } 2\xi \in d]. \end{aligned}$$

As “mousehood” is Π_2^1 , this latter displayed formula is now easily seen to be $\Sigma_3^1(a)$. Hence X turns out to be $\Sigma_3^1(a)$ in the codes, inside V_4 .

But because $(a_\gamma: \gamma < \omega_1)$ is uniquely determined given a , it is easy that X is now $\Pi_3^1(a)$ in the codes as well, inside V_4 . $\square$ (1.1)

There is also a *uniform* version of 1.1: if there is no inner model with a strong cardinal, then there is a generic extension by a set-sized reasonable forcing in which every $X \subset \omega_1$ will be Δ_3^1 in the codes. To prove this, instead of forcing with what we called P_4 over V_3 , we force Martin’s Axiom instead.

Proof of 1.2. Assuming that there is no inner model with a strong cardinal and building V_4 as in the last section, we have by Claim 5 that $H_{\omega_2} = J_{\omega_2}^{K(a)}$ in V_4 . Inside V_4 , we may thus define a well-ordering of the reals by $x < y$ iff

$$\exists \mathcal{M} [\mathcal{M} \text{ is an } a\text{-mouse and } x <_{\mathcal{M}} y].$$

(Here, $<_{\mathcal{M}}$ denotes the order of constructibility of $\mathcal{M}$.) Again using the fact that “mousehood” is Π_2^1 , this gives a $\Sigma_3^1(a)$ -wellordering of $\mathbb{R}$. But clearly $x < y$ can now also be written in a $\Pi_3^1(a)$ -fashion. $\square$ (1.2)

Proof of 1.3. Let us first suppose that there is a Π_3^1 -well-ordering of $\mathbb{R}$. This fact can be expressed by a Π_4^1 -statement Φ that is true in V . By adding ω_1 many Cohen reals with finite support we get a (c.c.c., hence proper, hence) reasonable extension $V[G]$ of V in which there is no projective well-ordering of the reals, so that Φ fails.

Thus if the assumption of 1.3 holds, then there can be no Π_3^1 -well-ordering of the reals in V . Now let us suppose that there is no inner model with a strong cardinal.

Then by 1.2 there is a reasonable extension $V[G]$ of V with a Π_3^1 - (in fact Δ_3^1 -) well-ordering of its reals. As above, this fact can be expressed by a Π_4^1 -statement Φ that is true in $V[G]$. But again by adding ω_1 many Cohen reals we get a reasonable extension $V[G][H]$ of $V[G]$ in which there is no projective well-ordering of the reals, so that Φ fails. Contradiction!

We have shown that there is an inner model with a strong cardinal. $\square$ (1.3)

By the remark at the end of the previous section, one can replace “reasonable” by “stationary preserving” in the statements of 1.1, 1.2, and 1.3.

4. FURTHER REMARKS

In this last section we want to point out a couple of things which are of related interest. The first one is an immediate corollary to 1.2, combined with an old argument of Harrington (cf. [3], pp. 575 ff.).

Fact 1. *Suppose that there is no inner model with a strong cardinal. Let δ be any ordinal. Then there is a generic extension by a set-sized reasonable forcing in which $\delta_4^1 > \max\{\delta, \aleph_3\}$.*

If V is not closed under $\sharp$'s, then a slight variation of the Harrington argument actually shows that we can make δ_3^1 as large as prescribed by a set-sized reasonable forcing. On the other hand, if $\mathbb{R}$ is closed under $\sharp$'s (i.e., if Π_1^1 -determinacy holds), then $\delta_3^1 \leq \aleph_3$.

Proof of Fact 1 (sketch). Going first to a reasonable extension provided by 1.2, we then run the Harrington construction as in [3], pp. 575 ff., say. As the two further forcings are c.c.c., hence proper, the final extension is a reasonable one. $\square$ (Fact 1, sketch)

Finally, we want to point out a “converse” to 1.2 which was noted in [13], Theorem 6 (b).

Fact 2. *Suppose that there is no inner model with a strong cardinal, and $\mathbb{R}$ is closed under $\sharp$'s (i.e., Π_1^1 -determinacy holds). Let $a \in \mathbb{R}$. If there is a $\Sigma_3^1(a)$ -well-ordering of $\mathbb{R}$, then in fact $\mathbb{R} = \mathbb{R} \cap K(a)$.*

This is false if $\mathbb{R}$ is not closed under $\sharp$'s. On the other hand, we can weaken the anti-large-cardinal assumption to “there is no inner model with a Woodin cardinal” if in addition we are willing to assume the existence of two measurable cardinals (in V) (this follows from Steel’s Σ_3^1 -correctness theorem, cf. [10]).

Proof of Fact 2 (sketch). Under the hypotheses of the theorem, by [12] there is a tree $T_2 \in K(a)$ projecting to the universal Π_2^1 -set of reals. (This tree gives Σ_3^1 -correctness of $K(a)$ in V .) But we can now run the Mansfield proof that if there is a $\Sigma_2^1(b)$ -well-ordering of the reals, then in fact $\mathbb{R} \subset L[b]$, for $b \in \mathbb{R}$ (cf. [3], Theorem 100 (c), p. 534), but with the Shoenfield tree replaced by T_2 . This gives the desired result. $\square$ (Fact 2, sketch)

As a by-product of this proof we get that if A is a $\Sigma_3^1(a)$ -set of reals, $a \in \mathbb{R}$, and $A \setminus K(a) \neq \emptyset$, then A in fact has a perfect subset. Hence if $\omega_1^{K(a)}$ is countable for every $a \in \mathbb{R}$, then every Σ_3^1 -set of reals has the perfect subset property. (This appears in [14], p. 286.)
