

SUPPORT VARIETIES FOR MODULES OVER CHEVALLEY GROUPS AND CLASSICAL LIE ALGEBRAS

JON F. CARLSON, ZONGZHU LIN, AND DANIEL K. NAKANO

ABSTRACT. Let G be a connected reductive algebraic group over an algebraically closed field of characteristic $p > 0$, G_1 be the first Frobenius kernel, and $G(\mathbb{F}_p)$ be the corresponding finite Chevalley group. Let M be a rational G -module. In this paper we relate the support variety of M over the first Frobenius kernel with the support variety of M over the group algebra $kG(\mathbb{F}_p)$. This provides an answer to a question of Parshall. Applications of our new techniques are presented, which allow us to extend results of Alperin-Mason and Janiszczak-Jantzen, and to calculate the dimensions of support varieties for finite Chevalley groups.

1. INTRODUCTION

1.1. Let G be a connected reductive k -algebraic group defined and split over the finite field \mathbb{F}_p of p elements where $k = \overline{\mathbb{F}}_p$. Let G_1 be the scheme theoretic kernel of the Frobenius map. The category of G_1 -modules is equivalent to the category of restricted modules for the restricted Lie algebra $\mathfrak{g} = \text{Lie } G$. On the other hand, let $G(\mathbb{F}_p)$ be the finite (untwisted) Chevalley group obtained by taking the \mathbb{F}_p -rational points of G . Given a rational G -module over k we can restrict the action to either G_1 or to $G(\mathbb{F}_p)$ (see Figure 1). Much effort has been made in trying to link the representation and cohomology theory for the finite group $G(\mathbb{F}_p)$ and the Frobenius kernel by using the ambient algebraic group. Even though the category of modules for the finite group and the Frobenius kernel share many intrinsic features, difficulties in making comparisons arise because there is no direct functorial relationship between these two categories.

In 1987, B. Parshall in an article in the Arcata Conference Proceedings entitled *Cohomology of Algebraic Groups* [P] stated two open problems where the first problem is a precursor to the second.

(1.1.1) If $M \in \text{mod}(G)$ such that M is projective as a G_1 -module, is M projective over $G(\mathbb{F}_p)$?

(1.1.2) Let $M \in \text{mod}(G)$. Can we relate the support variety of M for G_1 , $|G_1|_M$, with the support variety of M for the finite group $|G(\mathbb{F}_p)|_M$?

FIGURE 1

In [LN], the second and third authors showed that for $M \in \text{mod}(G)$,

$$\dim |G(\mathbb{F}_p)|_M \leq \frac{1}{2} \dim |G_1|_M.$$

This inequality was proved by developing a new approach to relate the cohomology theories of $G(\mathbb{F}_p)$ and G_1 . Thus, Statement (1.1.1) (known as the “Parshall conjecture”) is an immediate corollary of this result. Furthermore, in that paper it is shown that if $M \in \text{mod}(G)$ and the G -composition factors are p -bounded, then the converse to (1.1.1) also holds.

This paper is devoted to providing an affirmative answer to (1.1.2). The procedure for relating those varieties involves several new results and ideas. More precisely, through a series of works ([SFB], [FP2]) it is known that there is a G -equivariant isomorphism between $|G_1|_k$ and \mathcal{N}_1 , where \mathcal{N}_1 is the restricted nullcone. In [NPV], the Jantzen conjecture on support varieties was verified. As a consequence, it follows that $\mathcal{N}_1 = G \cdot \mathfrak{n}_J$ where \mathfrak{n}_J is the nil-radical of a parabolic Lie subalgebra \mathfrak{p}_J for some subset J of simple roots when the prime is good. This answers an old question of Friedlander and Parshall on the irreducibility of \mathcal{N}_1 . Recently, the authors and Parshall [CLNP] have determined representatives for the sets J and have computed the dimensions of \mathcal{N}_1 (for p good).

The aforementioned results are used in the following way. Let \mathcal{U}_1 be the closed subvariety of the unipotent variety \mathcal{U} consisting of elements of order 1 or p . Note that for $p \geq h$, $\mathcal{U}_1 = \mathcal{U}$ and $\mathcal{N}_1 = \mathcal{N}$ where \mathcal{N} is the ordinary nullcone. For p being good for G , by using our explicit description of $\mathcal{N}_1 = G \cdot \mathfrak{n}_J$, we verify conditions given by Seitz for the existence of an exponential map, $\exp : \mathfrak{n}_J \rightarrow U_J$ ($U_J = R_u(P_J)$) (Theorem 2). By using Springer isomorphisms between \mathcal{N} and \mathcal{U} and the classifications, we show that \mathcal{U}_1 is the closure of a Richardson class in \mathcal{U} whose description can be immediately read off from the results in [CLNP]. We then prove that there is an extension of this map to a G -equivariant isomorphism, $\exp : \mathcal{N}_1 \rightarrow \mathcal{U}_1$. However, we require that \mathcal{N}_1 be a normal variety. This condition is automatically satisfied when $p \geq h$. We should remark that our results also show that for $p \geq h$, the map \exp can be defined on the ordinary nullcone \mathcal{N} . For p good, Springer [Sp1] constructed a G -equivariant isomorphism between \mathcal{N} and \mathcal{U} . For the purposes of this paper (i.e., for obtaining an affirmative solution to (1.1.2)) this isomorphism does not have the required properties because this map is, in general, not compatible with the restriction maps given in Figure 1. The exponential map that we construct has the important properties that it respects the group operations and it preserves the centralizers in G and in \mathfrak{g} (Theorem 3).

We expect that \exp is the restriction of a Springer isomorphism. This is true when $p \geq h$. If this is the case, the normality condition on \mathcal{N}_1 can be dropped.

Furthermore, our construction is compatible with Seitz's construction of the good A_1 subgroups corresponding to each unipotent element of order p and provides an effective way to utilize the centralizers both in G and in \mathfrak{g} .

The exponential isomorphism mentioned above enables us to construct maps (up to an isogeny) ϕ and ψ between the cohomological varieties of \mathfrak{g} and $G(\mathbb{F}_p)$ which are finite onto their images, making the diagram in Figure 2 commute (Theorem 5). This allows us to identify the support variety $|G(\mathbb{F}_p)|_M$ as a subvariety of \mathcal{U}_1 inside the group G factored out by the action of $G(\mathbb{F}_p)$ (Corollary 1). Furthermore, we can also identify $|G(\mathbb{F}_p)|_M$ as a subvariety of $|G_1|_M/G(\mathbb{F}_p)$ for G -modules M whose weights are not too large. In general the algebraic group G does not act on $|G(\mathbb{F}_p)|_M$. Nevertheless, the existence of these maps enables us to use the rich geometric theory of nilpotent orbits in \mathfrak{g} to obtain results for finite groups. Applications will be presented in the last section of the paper.

$$\begin{array}{ccc}
 & \mathcal{U}_1/G(\mathbb{F}_p) & \\
 \phi \nearrow & & \searrow \bar{\log} \\
 |G(\mathbb{F}_p)|_k & \xrightarrow{\psi} & |G_1|_k/G(\mathbb{F}_p)
 \end{array}$$

FIGURE 2

1.2. The paper is organized as follows. In Section 2, we apply the results of [CLNP] and [NPV] to extend the exponential isomorphism $\exp : \mathfrak{n}_J \rightarrow \mathcal{U}_J$ to a G -equivariant isomorphism $\exp : \mathcal{N}_1 \rightarrow \mathcal{U}_1$. In Section 3, using the exponential map \exp , we define the notion of \mathbb{F}_p -expressible nilpotent elements and \mathbb{F}_p -expressible unipotent elements via elementary abelian p -subgroups. These varieties behave well under the exponential map between the unipotent and nilpotent varieties. In Section 4, we show how to map an elementary abelian p -subgroup in $G(\mathbb{F}_p)$ into the unipotent variety using the exponential map constructed in Section 2. This will allow us to define a map, which is finite onto its image, from the cohomological variety $G(\mathbb{F}_p)$ into \mathcal{U}_1 factored out by the conjugation action of the finite group $G(\mathbb{F}_p)$. The quotient space $\mathcal{U}_1/G(\mathbb{F}_p)$ can thus be viewed as a “model” for the theory of supports for $G(\mathbb{F}_p)$. The logarithm map can also be used to construct a finite map from the support variety of a module for $G(\mathbb{F}_p)$ into $\mathcal{N}_1/G(\mathbb{F}_p)$. The images of these maps are identified at the end of the section by using our definition of \mathbb{F}_p -expressibility. Recently Friedlander and Pevtsova, [FPe, Prop. 5.8], demonstrated that the maps given above are compatible with their “support space” point of view.

In the final section, applications are provided which are both conceptual as well as computational. We indicate how earlier results of Alperin and Mason, and Janiszczak and Jantzen for finite groups $G(\mathbb{F}_q)$ can be further extended by using the theory of nilpotent orbits in \mathfrak{g} for the groups $G(\mathbb{F}_p)$. Furthermore, we demonstrate how the dimensions of the support varieties of G -modules over finite Chevalley groups can be computed once their support varieties over G_1 are known. In particular, we compute the complexity of the simple modules for $G(\mathbb{F}_p)$ for all

rank two simple groups. Also, we determine the complexity for induced modules $H^0(\lambda)$ over $\mathrm{GL}_n(\mathbb{F}_p)$ for $n \leq 7$ when the highest weights are not large.

A Chevalley group in this paper means an untwisted group. The twisted case is not treated in this paper. It seems as though a different approach will be necessary to prove similar results for modules over higher Frobenius kernels and $G(\mathbb{F}_{p^r})$ for $r > 1$.

1.3. Notation and conventions. Throughout this paper let k be an algebraically closed field of characteristic $p > 0$ which contains the finite field \mathbb{F}_p of p elements. Let G be a simple algebraic k -group defined and split over the prime field \mathbb{F}_p having root system Φ with respect to a maximal split torus T . Let Π be the set of simple roots and Φ^+ (resp. Φ^-) be the positive (resp. negative) roots. The Coxeter number of Φ is denoted by h . Let B be the Borel subgroup containing T defined by Φ^- . Furthermore, let $X(T)$ be the integral weight lattice obtained from T . If $\alpha^\vee = 2\alpha/\langle\alpha, \alpha\rangle$ is the coroot corresponding to $\alpha \in \Phi$, then the set of dominant integral weights is defined by

$$X(T)_+ = \{\lambda \in X(T) : 0 \leq \langle\lambda, \alpha^\vee\rangle \text{ for all } \alpha \in \Pi\}.$$

The Weyl group W is the group generated by reflections associated to the root system Φ , and $W_p = W \ltimes p\mathbb{Z}\Phi$ is the affine Weyl group associated to the prime p . Furthermore, the set of p -restricted weights is

$$X_1(T) = \{\lambda \in X(T) : 0 \leq \langle\lambda, \alpha^\vee\rangle < p \text{ for all } \alpha \in \Pi\}.$$

The Weyl group W (affine Weyl group W_p) acts on $X(T)$ naturally with the “dot action” defined by $w \cdot \lambda = w(\lambda + \rho) - \rho$ where $w \in W$ ($w \in W_p$), $\lambda \in X(T)$, and ρ is the half sum of positive roots. The simple modules will be denoted by $L(\lambda)$ and the induced modules by $H^0(\lambda) = \mathrm{ind}_B^G \lambda$ for $\lambda \in X(T)_+$.

Let $\mathfrak{g} = \mathrm{Lie}(G)$ be the Lie algebra of G . Then \mathfrak{g} is a restricted Lie algebra with p th power map $[p]$. The variety of nilpotent elements of \mathfrak{g} is called the nullcone and is denoted by \mathcal{N} . The restricted nullcone is defined as $\mathcal{N}_1 = \{x \in \mathfrak{g} : x^{[p]} = 0\}$. Let \mathcal{U} be the set of unipotent elements in G and let the p -unipotent variety \mathcal{U}_1 be defined as $\mathcal{U}_1 = \{x \in G : x^p = 1\}$.

Let H be an affine algebraic group scheme over k and let $H_1 = \ker(Fr)$. Here $Fr : H \rightarrow H^{(1)}$ is the Frobenius map. There is a categorical equivalence between restricted $\mathrm{Lie}(H)$ -modules and H_1 -modules (see [Jan1, I. Ch.9]).

For a finite k -group scheme K , the cohomology ring $R = H^{2\bullet}(K, k)$ is a commutative, finitely generated k -algebra [FS]. If $M \in \mathrm{mod}(K)$, the *support variety* of M , $|K|_M$, is the maximal ideal spectrum of R/J_M where J_M is the annihilator of $\mathrm{Ext}_K^\bullet(M, M)$ in R . The dimension of $|K|_M$ can be interpreted as the complexity of the module M [Ben1, §5.7]. In this paper we will be interested in the cases when $K = G(\mathbb{F}_p)$ and $K = G_1$.

2. AN EXPONENTIAL MAP DEFINED ON THE RESTRICTED NULLCONE

2.1. Let R be a commutative ring and let X be an R -scheme. For any homomorphism $R \rightarrow A$ of commutative rings, let $X_A = X \otimes_R A$ denote the A -scheme defined via base change. If $S \rightarrow R$ is a homomorphism of commutative rings, then we say that X has an S -structure if there is an S -scheme X_S such that $X = X_S \otimes_S R$. If

$\phi : X \rightarrow Y$ is a morphism of R -schemes, then we denote by $\phi_A = \phi \otimes_R A : X_A \rightarrow Y_A$ the A -morphism of A -schemes. If both X and Y are R -schemes with S -structures X_S and Y_S respectively, we say the morphism ϕ is defined over S if there is an S -morphism $\phi_S : X_S \rightarrow Y_S$ of S -schemes such that $\phi = \phi_S \otimes_S R$. For an R -scheme X and any R -algebra A , we set $X(A) = \text{Mor}_{R\text{-sch}}(\text{Spec}(A), X)$ to be the set of all A -rational points. In particular, when X has an S -structure for a subring S of R , we write $X(S)$ as the set of S -rational points of X_S instead of $X_S(S)$. When $R = k$ is an algebraically closed field and X is an algebraic k -variety, we identify X with the set of all closed k -rational points instead of writing $X(k)$. The terminology and conventions are provided for the reader in [Jan1] and [Sp3].

Lemma 1. *Let F be a perfect field. Suppose that $\phi : X \rightarrow Y$ is an F -morphism of algebraic F -varieties and that k is an algebraically closed field containing F as a subfield. Then*

- (a) *for any closed subvariety $V \subseteq Y_k$ defined over F , $\phi_k^{-1}(V) \subseteq X_k$ is a closed subvariety of X_k defined over F , and*
- (b) *if ϕ is a constant morphism of F -varieties, then so is ϕ_k .*

Proof. Let $\Gamma_\phi = \{(x, \phi(x)) \in X_k \times Y_k \mid x \in X_k\}$ be the graph of ϕ . Then Γ_ϕ is a closed F -subvariety of $X \times Y$. The projections $p_1 : X \times Y \rightarrow X$ and $p_2 : X \times Y \rightarrow Y$ are defined over F and $p_1 : \Gamma_\phi \rightarrow X$ is an isomorphism (defined over F). Under this isomorphism p_1 , we have $\phi^{-1}(V)$ isomorphic to $\Gamma_\phi \cap (X \times V)$, which is a closed F -subvariety of Γ_ϕ by [Sp2, 11.2.13]. This proves (a).

To see (b), we recall that ϕ_k is a constant if and only if $\phi_k^* : k[Y] \rightarrow k[X]$ factors through the embedding $k \subseteq k[X]$ (we can assume that X and Y are affine). It follows that ϕ_k is constant because $\phi_F^* : F[Y] \rightarrow F[X]$ factors through $F \subseteq F[X]$ and $\phi_k^* = \phi_F^* \otimes_F 1$. \square

2.2. Let $\mathfrak{g}_{\mathbb{C}}$ be a complex semisimple Lie algebra. Fix a Chevalley basis and let $\mathfrak{g}(\mathbb{Z})$ be the \mathbb{Z} -span of the Chevalley basis. Set $\mathfrak{g} := k \otimes_{\mathbb{Z}} \mathfrak{g}(\mathbb{Z})$ and $\mathfrak{g}(\mathbb{F}_p) := \mathbb{F}_p \otimes_{\mathbb{Z}} \mathfrak{g}(\mathbb{Z})$. When $\mathfrak{g}_{\mathbb{C}}$ is regarded as an affine \mathbb{C} -variety, the Chevalley basis defines a \mathbb{Z} -structure $\mathfrak{g}_{\mathbb{Z}}$ on \mathfrak{g} . Thus $\mathfrak{g}(\mathbb{Z})$ is the set of \mathbb{Z} -rational points of the \mathbb{Z} -scheme $\mathfrak{g}_{\mathbb{Z}}$. Similarly, we use $\mathfrak{g}_{\mathbb{F}_p}$ to denote the \mathbb{F}_p -scheme which gives an \mathbb{F}_p -structure on the k -variety \mathfrak{g} and use $\mathfrak{g}(\mathbb{F}_p)$ to denote the set of \mathbb{F}_p -rational points of $\mathfrak{g}_{\mathbb{F}_p}$. We now fix an algebraically closed field k of characteristic $p > 0$. Let G be a semisimple algebraic group over k with a split \mathbb{F}_p -form $G_{\mathbb{F}_p}$ such that $\mathfrak{g}(\mathbb{F}_p)$ is the Lie algebra $\text{Lie}(G_{\mathbb{F}_p})$ over \mathbb{F}_p in $\mathfrak{g} = \text{Lie}(G)$. The reader is referred to [Jan1], [Bo, 18.6], and [Sp2] for further details on algebraic groups and group schemes.

2.3. Let G be a semisimple algebraic group such that $G_{sc} \rightarrow G$ is separable (i.e., $\text{Lie}(G_{sc}) \rightarrow \text{Lie}(G)$ is surjective). Springer ([Sp1, Thm. 3.1], [SS, III, 3.12]) constructed a logarithmic map $\log_s : \mathcal{U} \rightarrow \mathcal{N}$ which is G -equivariant. Fix a regular unipotent element u and regular nilpotent element x such that $C_G(x) = C_G(u)$, and let \log_s be such that $\log_s(u) = x$. This defines an isomorphism between the open sets of regular unipotent and nilpotent elements. The map \log_s is defined over the ring $\mathbb{Z}_{(p)}$ (p is good), and \log_s can be extended to a homeomorphism $\mathcal{U} \rightarrow \mathcal{N}$. It is now known that \log_s is an isomorphism of G -varieties for good characteristics since \mathcal{N} is normal [Hum4, p. 118]. However, the map \log_s is not uniquely defined and depends on the choice of a regular unipotent element u in \mathcal{U} and a regular nilpotent element $x \in \mathfrak{n}$ such that $C_G(u) = C_G(x)$. For $J \subset \Pi$, let P_J be the standard

parabolic subgroup of G containing the Borel subgroup B , and let $P_J = L_J U_J$ with L_J being a Levi subgroup and U_J the unipotent radical of P_J . Note that under the adjoint action of G , we have $\text{Stab}_G(U_J) = P_J$ and $\text{Stab}_G(\mathfrak{n}_J) = P_J$. Also, we have $\log_s(U) = \mathfrak{n}$. Let \mathcal{O}_J^u (resp. \mathcal{O}_J^n) be the unipotent (resp. nilpotent) Richardson orbit corresponding to P_J . We recall that \mathcal{O}_J^u (resp. \mathcal{O}_J^n) is the unique G -orbit such that $U_J \cap \mathcal{O}_J^u$ (resp. $\mathfrak{n}_J \cap \mathcal{O}_J^n$) is a single open dense P_J -orbit in U_J (resp. \mathfrak{n}_J).

Proposition 1. $\log_s(U_J) = \mathfrak{n}_J$ and $\log_s(\mathcal{O}_J^u) = \mathcal{O}_J^n$.

Proof. Let $U_L = U \cap L_J$ be the unipotent radical of a Borel subgroup of L_J and $\mathfrak{n}_L = \text{Lie}(U_L)$. Let $\phi : P_J \rightarrow L_J$ be the quotient morphism, and let $d\phi : \text{Lie}(P_J) \rightarrow \text{Lie}(L_J)$ be the differential of ϕ . Under the adjoint action, both ϕ and $d\phi$ are P_J -equivariant with P_J acting on L_J and $\text{Lie}(L_J)$ by way of the quotient map $P_J/U_J = L_J$. From the definition, we have that $\phi(U) = U_L$ and $d\phi(\mathfrak{n}) = \mathfrak{n}_J$. Let $Y = \log_s(U_J)$. Then $Y \subseteq \mathfrak{n}$ is a closed P_J -stable irreducible subvariety. Let $X = d\phi(Y)$. Then X is an irreducible P_J -stable subvariety and thus is the closure of a nilpotent L_J -orbit in $\text{Lie}(L_J)$. Since L_J is reductive, then $\dim X = 2 \dim(X \cap \mathfrak{n}_L)$. However, $X \subseteq d\phi(\mathfrak{n}) = \mathfrak{n}_L$, and we have $X = X \cap \mathfrak{n}_L$ and $\dim X = \dim(X \cap \mathfrak{n}_L)$. This forces that $\dim X = 0$ and $X = \{0\}$, (i.e., the only zero-dimensional nilpotent orbit). Hence, $Y \subset \ker(d\phi) = \mathfrak{n}_J$. The map $\log_s : U_J \rightarrow \mathfrak{n}_J$ is a P_J -equivariant isomorphism and thus sends the unique open P_J -orbit to the unique open P_J -orbit. In particular $\log_s(\mathcal{O}_J^u) = \mathcal{O}_J^n$. \square

One of the referees pointed out a different way, using [McN2, Rem. 10], to prove Proposition 1. In fact this argument will prove that for any G -equivariant isomorphism $\phi : \mathcal{U} \rightarrow \mathcal{N}$, for any parabolic (in particular Borel) subgroup P , Proposition 1 holds with \log_s replaced by ϕ by using the description of parabolic subgroups given in [Sp2, 8.4.5, 8.4.6(5)]. The Springer isomorphism assumes that $\phi(U) = \mathfrak{n}$.

The unipotent classes in G and the nilpotent orbits in \mathfrak{g} in characteristic zero are labeled in terms of weighted Dynkin diagrams (cf. [C, Ch. 5, Ch. 13]). This classification still works in good characteristics. For classical groups, the weighted Dynkin diagrams are determined by Jordan types of the unipotent (nilpotent) elements. For exceptional groups, they are listed in the tables in [C, Ch. 13].

Theorem 1. *Let G be a connected simple group and p be good for G . If $\phi : \mathcal{U} \rightarrow \mathcal{N}$ is a G -equivariant isomorphism, then*

- (a) ϕ is a Springer isomorphism.
- (b) The one-to-one correspondence defined by ϕ between the set of all unipotent conjugacy classes and the set of all nilpotent G -orbits preserves the labeling of unipotent classes and nilpotent orbits in terms of weighted-Dynkin diagrams as in [C] and, in particular, is independent of ϕ .
- (c) For any $r \geq 1$ and $u \in \mathcal{U}$, $u^{p^r} = 1$ if and only if $(\phi(u))^{[p]^r} = 0$.
- (d) For each $r \geq 1$, the closed subvarieties $\mathcal{U}_r = \{u \in \mathcal{U} \mid u^{p^r} = 1\}$ and $\mathcal{N}_r = \{x \in \mathcal{N} \mid x^{[p]^r} = 0\}$ are isomorphic under ϕ and are irreducible.

Proof. (a) By Proposition 1 or [McN2, Rem. 10], ϕ in particular sends a regular unipotent element to a regular nilpotent element such that $\phi(U) = \mathfrak{n}$ for any Borel subgroup B . Thus ϕ is a Springer isomorphism.

(b) The independence of ϕ follows from (a) and a result of Serre (Appendix to [McN2]). The correspondence is independent of the choice of Springer isomorphism.

First, by the proposition above, any isomorphism ϕ sends a Richardson unipotent class to a Richardson nilpotent orbit of the same type. Since the correspondence of orbits preserves the closure relation, the dimension of the orbit, and the stabilizer subgroup of G , it also preserves the component group and the Cartan type of each orbit. In particular, any isomorphism ϕ has to send regular unipotent elements to regular nilpotent elements (also note that regular orbits are Richardson orbits).

For classical groups, Springer has constructed explicit isomorphisms. In cases of type A_l , the map $u \mapsto u - 1$ is a G -equivariant isomorphism. Note that the unipotent matrix u and the nilpotent matrix $u - 1$ give rise to the same partition and the same corresponding weighted Dynkin diagram. This also follows from the fact that all nilpotent orbits (unipotent classes) are Richardson. For symplectic and orthogonal groups, an isomorphism is given by the Cayley transformation $u \mapsto (1 - u)(1 + u)^{-1}$ ($p \neq 2$). By expressing the matrix u in its Jordan form, we can easily see that the nilpotent element $(1 - u)(1 + u)^{-1}$ is associated to the same partition. The weighted Dynkin diagrams are uniquely determined by the partition corresponding to the nilpotent (unipotent) element unless the group is $G = SO_{2l}$ and the partition consists of all even parts. In this exceptional case, each very even partition corresponds to two different orbits. Both orbits are even and are Richardson orbits. Now Proposition 1 implies that the isomorphism will preserve the weighted Dynkin diagrams in the list of unipotent classes and nilpotent orbits.

For exceptional groups, we can check the list of the properties: dimension, the Levi type of the centralizer, the dimension of unipotent radical of the centralizer and the component group of the centralizer. By inspecting all unipotent classes listed in [C] with the above listed properties, we find that there are only a few cases when two orbits have the identical properties listed above. But in each case, we can find (by inspecting the Hasse diagrams in [C]) a Richardson class which contains only one such orbit in its closure. This also shows that the correspondence is independent of the isomorphism without using Serre's result. Therefore, the correspondence preserves the weighted Dynkin diagrams for exceptional groups.

(c) For classical groups, the conclusion follows from (b) and the fact that u and $\log_s(u)$ determine the same partition. For exceptional groups we use the labeling of the unipotent classes and nilpotent orbits. Using the Bala-Carter classification, the label gives the Levi factor and the distinguished parabolic subgroup of the derived group of the Levi factor. The order formula for distinguished unipotent elements was proved by Testerman [T2] and the nilpotency class of a distinguished nilpotent element was provided by McNinch [McN1]. Using these results, a direct comparison for each weighted Dynkin diagram will yield the conclusion.

(d) The isomorphism is a direct result of part (c). The irreducibility follows from [CLNP, Thm. 3.10] and [UGA, Thm. 3.2, §4.1]. \square

We remark that there is a more conceptual proof to the theorem without using Serre's result. In fact, one can use the Bala-Carter classification of unipotent and nilpotent orbits in terms of conjugacy classes of the pairs (L, P) where L is a Levi subgroup and P is a distinguished parabolic subgroup of the semisimple subgroup $L' = [L, L]$. For each nilpotent (or unipotent) element x , $L = C_G(S)$ with S being a maximal torus of $\text{Stab}_G(x)$ and x being a nilpotent (unipotent) Richardson element

of P . Thus any G -equivariant isomorphism $\phi : \mathcal{U} \rightarrow \mathcal{N}$ would give the same G -conjugacy class of the distinguished pair (L, P) . Therefore, any isomorphism ϕ (not necessarily a Springer isomorphism) will induce the same correspondence between unipotent classes and nilpotent orbits. We also note that part (c) is proved in [McN1].

2.4. It is shown in [NPV] that $\mathcal{N}_1 = G \cdot \mathfrak{n}_J$ for a subset $J \subseteq \Pi$ of simple roots corresponding to a parabolic subalgebra \mathfrak{p}_J where \mathfrak{n}_J is the nil-radical of \mathfrak{p}_J . Let P_J and U_J be the corresponding parabolic and unipotent subgroups of G such that $U_J = R_u(P_J)$. In [CLNP] representatives for the sets J have been determined. Following Testerman [T1], we define, for each subset J of Π , the function $\text{ht}_J : \mathbb{Z}\Phi \rightarrow \mathbb{Z}$ by $\text{ht}_J(\sum_{\alpha \in \Pi} a_\alpha \alpha) = \sum_{\alpha \notin J} a_\alpha$. In particular, the unipotent group U_J has nilpotency class at most $\text{ht}_J(\alpha_0)$, where α_0 is the highest positive root. Let $\mathcal{U}_1 = \{u \in G \mid u^p = 1\}$. Then \mathcal{U}_1 is a closed subvariety of \mathcal{U} .

Theorem 2. *Let G be a simple algebraic group and let p be a good prime. There exists $J \subseteq \Pi$ such that $\mathcal{N}_1 = G \cdot \mathfrak{n}_J$ and the following hold.*

- (a) *For any $\alpha \in \Phi^+$, $\text{ht}_J(\alpha) < p$,*
- (b) *the Lie algebra \mathfrak{n}_J has nilpotency less than p , and*
- (c) *$\log_s : \mathcal{U}_1 \rightarrow \mathcal{N}_1$ is a G -equivariant isomorphism. In particular $\mathcal{U}_1 = G \cdot U_J$.*

Proof. Note that $[\mathfrak{g}_\alpha, \mathfrak{g}_\beta] \subseteq \mathfrak{g}_{\alpha+\beta}$ for all $\alpha, \beta \in \Phi^+$, so (b) follows from (a). To prove (a) we use the description of J given in [CLNP]. If $p \geq h$, then (a) is true because all roots α have height at most $h-1$. Assume that $p < h$. For type A_l , all roots in Φ^+ have coefficients at most 1 and $|\Pi \setminus J| = p-1$ [CLNP, Thm 3.3]. For type B_l, C_l , we use [CLNP, Thm. 3.8] to see that $|\Pi \setminus J| \leq \frac{p-1}{2}$ and the fact that all roots in Φ^+ have coefficients at most 2. For type D_l , we have $|\Pi \setminus J| \leq \frac{p-1}{2}$ if J contains both α_{l-1} and α_l and $|\Pi \setminus J| \leq \frac{p-1}{2}$ otherwise. Now (a) follows from the fact that the coefficients of α_{l-1} and α_l are at most 1 in the case of type D_l .

For the exceptional groups, the sets J are determined in [CLNP, 4.4]. For the reader's convenience, we list them here together with α_0 . We can read off $\text{ht}_J(\alpha_0)$ from the tables as the sum of the coefficients in α_0 of simple roots not in J . In each case, we have $\text{ht}_J(\alpha_0) < p$.

Type E_6 : $\alpha_0 = \alpha_1 + 2\alpha_2 + 2\alpha_3 + 3\alpha_4 + 2\alpha_5 + \alpha_6$.

For part (c), the fact that \log_s restricts to a G -equivariant isomorphism follows from Theorem 1, and the statement that $\mathcal{U}_1 = G \cdot U_J$ is a consequence of Proposition 1. \square

We remark that although \log_s is a G -equivariant isomorphism between \mathcal{U}_1 and \mathcal{N}_1 , in general, \log_s does not preserve the group structure when restricted to unipotent abelian subgroups. For example, the Springer map used in the proof of Theorem 1 is not a group homomorphism in general. For the remainder of this section we investigate the exponential maps, \exp , which are only defined over nilpotent Lie subalgebras of nilpotency less than p [Sei]. The advantage of the exponential map is that it is a group homomorphism when restricted to certain unipotent subgroups.

2.5. The subgroup U_J of G has a \mathbb{Z} -structure with the \mathbb{Z} -form $(U_J)_{\mathbb{Z}}$. The Lie algebra \mathfrak{n}_J also has a \mathbb{Z} -structure $(\mathfrak{n}_J)_{\mathbb{Z}}$ as a scheme. Because the nilpotency class of \mathfrak{n}_J is less than p , by Seitz [Sei, Prop. 5.1-5.3] (with $U_J = U_{\Gamma}$ and $\Gamma = \Phi^+ \setminus \Phi_J^+$, in the notation of [Sei, Prop. 5.1]) there is an isomorphism of algebraic k -varieties $\exp : \mathfrak{n}_J \rightarrow U_J$, which is defined over the localization $\mathbb{Z}_{(p)}$. For J satisfying the conditions of Theorem 2, we can check case by case that, for all $x \in \mathfrak{n}_J(\mathbb{Z}_{(p)})$, the conditions of [T2, Lem. 1.4] are satisfied, except in a few cases for which we cannot find J_1 and J_2 . But in those cases, one of the e_1 and e_2 can be chosen as a root vector, and the proof of [T2, Lem. 1.4] still works. When G is of adjoint type, the map \exp was established in [T2, Lem. 1.1] for all $x \in \mathfrak{n}_J(\mathbb{Z}_{(p)})$. The condition required for [T2, Lem. 1.1] is guaranteed in [T2, Lem. 1.4]. For simply connected groups, the map \exp is first defined over the field of complex numbers via the usual exponential map. Seitz [Sei, Prop 5.1] proved that the exponential map is actually defined over $\mathbb{Z}_{(p)}$. In particular, given any $x \in \mathfrak{n}_J(\mathbb{Z}_{(p)})$ and any rational $G_{\mathbb{Z}_{(p)}}$ -module $M(\mathbb{Z}_{(p)})$, the action of $\exp(x)$ on $M(\mathbb{Z}_{(p)})$ is given by $\exp(x) = \sum_{n=0}^{\infty} x^n/n!$ with $x^n/n!$ being elements of the distribution algebra of $(U_J)_{\mathbb{Z}_{(p)}}$ (see [Jan1, I, Ch. 7]). For any $x \in \mathfrak{n}_J(\mathbb{F}_p)$, we still use $x^{(n)}$ to denote the image of $x^n/n!$ in the

distribution algebra of $(U_J)_{\mathbb{F}_p}$ for some $z \in \mathfrak{n}_J(\mathbb{Z}_{(p)})$ which has image x by reduction modulo p . The following proposition indicates how these structures behave under base change.

Proposition 2. *Let $x_1, x_2 \in \mathfrak{n}_J(\mathbb{F}_p)$ such that $[x_1, x_2] = 0$. Suppose that M is a rational G -module with a $G_{\mathbb{F}_p}$ -structure, $M_{\mathbb{F}_p}$. Then for t_1 and t_2 in k , the action of $\exp(t_1x_1 + t_2x_2)$ on $M = M(\mathbb{F}_p) \otimes_{\mathbb{F}_p} k$ is given by the exponential map*

$$\exp(t_1x_1 + t_2x_2) = \sum_{n,m=0}^{\infty} (x_1^{(n)}x_2^{(m)}) \otimes t_1^n t_2^m.$$

Proof. Note that \mathfrak{n}_J is an algebraic group with multiplication given by the Hausdorff formula [Ser, IV, 8] and \exp is an isomorphism of algebraic groups $\mathfrak{n}_J \rightarrow U_J$ by [Sei, Prop. 5.2]. Since $[x_1, x_2] = 0$, the Hausdorff formula implies $\exp(t_1x_1 + t_2x_2) = \exp(t_1x_1)\exp(t_2x_2)$ in U_J . Now we see from the definition of the exponential map, \exp , that the formula holds in $\text{End}_k(M)$ (see [Jan1, I, 7.4(1)]). \square

2.6. It is well known that $N_G(\mathfrak{n}_J) = N_G(U_J) = P_J$ and that $N_G(\mathfrak{n}_J)$ is a connected closed subgroup of G and defined over $\mathbb{Z}_{(p)}$ (see [Jan1, 2.6], for example). The following proposition lists some properties of the exponential map. A subgroup A of G of type A_1 is called a good A_1 -subgroup if all weights of $\text{Lie}(G)$ are at most $2(p-1)$ as an A -module. The 1-dimensional unipotent algebraic group G_a has Lie algebra $k\gamma^{(1)}$ and its distribution algebra $\text{Dist}(G_a)$ has a k -basis $\{\gamma^{(i)} \mid i = 0, 1, 2, \dots\}$ which satisfies $\gamma^{(i)}\gamma^{(j)} = \binom{i+j}{i}\gamma^{(i+j)}$.

Lemma 2. [Sei] *Let p be a good prime for the group G . For any $1 \neq u \in \mathcal{U}_1$, there exists a unique homomorphism $f_u : G_a \rightarrow G$ such that $f_u(G_a) = U_A$ is the unipotent subgroup of a Borel subgroup B_A of a good A_1 -subgroup A of G with the following properties:*

- (i) $f_u(1) = u$;
- (ii) $df_u(\gamma^{(1)}) = e$ is a basis for $\text{Lie}(U_A)$ and, identifying $\text{Lie}(U_A)$ with G_a under the map $e \mapsto 1$, the homomorphism $f_u : \text{Lie}(U_A) \rightarrow U$ has differential $df_u = 1$ on $\text{Lie}(U_A)$;
- (iii) $C_G(u) = C_G(U_A) = C_G(\text{Lie}(U_A))$.

Proposition 3. *Let p be good and $\mathcal{N}_1 = G \cdot \mathfrak{n}_J$.*

- (a) [Sei, 5.3] *The isomorphism $\exp : \mathfrak{n}_J \rightarrow U_J$ is invariant under the adjoint action of P_J and the differential $d\exp : \mathfrak{n}_J \rightarrow \mathfrak{n}_J$ is the identity map.*
- (b) [Sei, Lem. 6.3] $C_{P_J}(x) = C_{P_J}(\exp(x))$ for all $x \in \mathfrak{n}_J$.

2.7. One of the consequences of Theorem 2(c) is that for each unipotent element $u \in G$ with $u^p = 1$, we can assume $u \in U_A \subseteq U_J$ with $\text{Lie}(U_A) = ke \subseteq \mathfrak{n}_J$, where U_A is the unipotent subgroup of a Borel subgroup of a good A_1 -subgroup of G . By Lemma 2(iii), we have $C_G(u) = C_G(ke)$.

Let $x \in \mathfrak{n}_J(\mathbb{F}_p)$ be an \mathbb{F}_p -rational point in \mathfrak{n}_J . The centralizer $C_G(x)$ is a closed subgroup of G defined over \mathbb{F}_p [Sp2, 11.2.1]. Thus the map $G \rightarrow G \cdot x$ of algebraic varieties is defined over \mathbb{F}_p . We want to extend the map $\exp : \mathfrak{n}_J \rightarrow U_J$ to a map $\exp : \mathcal{N}_1 \rightarrow \mathcal{U}_1$. The first step is to compare $C_G(x)$ with $C_G(\exp(x))$ for $x \in \mathfrak{n}_J$.

Proposition 4. *Let $u \in U_A \subseteq U_J$ be an element where U_A is the unipotent radical of a Borel subgroup B_A of a good A_1 -subgroup of G .*

- (a) *If $B_A \subseteq P_J$, then $C_G(x) = C_G(\exp(x))$ for each $x \in \text{Lie}(U_A)$.*

- (b) For good primes p , if $x \in \mathfrak{n}_J$ is a Richardson element for P_J , then $C_G(x) = C_G(\exp(x))$.
- (c) If either \mathcal{N}_1 or \mathcal{U}_1 is a normal variety, then for all $x \in \mathcal{N}_1$, we have $C_G(x) = C_G(\exp(x))$.

Proof. (a) Let $f : G_a \rightarrow U_A$ be an isomorphism of algebraic groups. Since $U_A \subseteq U_J$, Proposition 5.4 of [Sei] implies that there are $e_i \in \mathfrak{n}_J$ ($i = 0, 1, 2, \dots$) such that $[e_i, e_j] = 0$ and $f(t) = \exp(te_0) \exp(t^p e_1) \cdots$. Let $B_A = U_A T_A$ be a Borel subgroup of A where $T_A \subseteq P_J$ is a maximal torus of A . Note each factor of $f(t)$ is invariant under the T_A -action. Using the ideas in the proof of [Sei, Prop. 5.5], we show that e_i has T_A -weight $2p^i$. Since A is a good A_1 , $e_i = 0$ for all $i \geq 1$ and $f(t) = \exp(te_0)$ for some $e_0 \in \mathfrak{n}_J$. Moreover, $d\exp$ is the identity on \mathfrak{n}_J by [Sei, Prop. 5.3]. Thus, $e_0 \in \text{Lie}(U_A)$ and $\exp(e_0) = u$. Now (a) follows from [Sei, Prop. 6.1] (cf. Lemma 2(iii)).

(b) Let $x \in \mathfrak{n}_J$ be a Richardson element of P_J . Because $\exp_x : G_a \rightarrow U_J$ defined by $\exp_x(t) = \exp(tx)$ is a homomorphism of algebraic groups whose image $\exp_x(k) \subseteq U_J$ is a closed subgroup and because $\text{Lie}(\exp_x(k)) = kx$, we have $C_G(x) \supseteq C_G(\exp(x))$. Let $x_1 = \log_s(\exp(x))$, where \log_s is a Springer isomorphism. By Proposition 1, we have $x_1 \in \mathfrak{n}_J$ is a Richardson element. Thus there exists $g_0 \in P_J$ such that $x = g_0 \cdot x_1$. Since \log_s is a G -equivariant morphism, we have that

$$C_G(\exp(x)) = C_G(\log_s(\exp(x))) = C_G(x_1) = g_0^{-1} C_G(x) g_0.$$

Using the inclusion $C_G(\exp(x)) \subseteq C_G(x)$, we see that $g_0 \in N_G(C_G(x))$ and $C_G(x) = C_G(\exp(x))$.

(c) From part (b), $\exp : G \cdot x \rightarrow G \cdot \exp(x)$ is a G -equivariant isomorphism (since its differential is not zero). Under the Springer isomorphism, both $G \cdot \mathfrak{n}_J$ and $G \cdot U_J$ are normal algebraic varieties. Since the complement of the dense G -orbit in $G \cdot \mathfrak{n}_J$ has codimension at least 2 [Jan4, 8.4], by (b) the isomorphism on the Richardson orbit induced by \exp extends uniquely to an isomorphism $\exp : \mathcal{N}_1 \rightarrow \mathcal{U}_1$. The map $\exp : \mathcal{N}_1 \rightarrow \mathcal{U}_1$ is G -equivariant since its restriction to the open orbit is G -equivariant. \square

We expect that condition (a) holds for every $U_A \subseteq U_J$. This condition is equivalent to the fact that x has an associated character (see [Jan4, 5.3]) with image in P_J . In many cases we know that \mathcal{N}_1 is normal. For groups of type A , Donkin [D] showed that all orbit closures are normal. Furthermore, the closures of the regular and subregular orbits [KLT] are normal. Thomsen [Th] has also provided a method to show that \mathcal{N}_1 is normal for several cases for exceptional groups. It is also an interesting question to know whether $\exp : \mathfrak{n}_J \rightarrow U_J$ is the restriction of a Springer isomorphism. If this is the case, the assumption of the normality of \mathcal{N}_1 can be dropped.

2.8. For any $x \in \mathfrak{n}_J(\mathbb{F}_p)$, we define $\psi_x : G \rightarrow \mathcal{N}_1$ by $\psi_x(g) = g \cdot x$. The morphism ψ_x is defined over \mathbb{F}_p . We define $V_x = \{g \in G \mid g \cdot x \in \mathfrak{n}_J\}$. Then $V_x = \psi_x^{-1}(\mathfrak{n}_J)$ is a closed subvariety defined over \mathbb{F}_p by Lemma 1. For any $g \in V_x$ set $\phi_x(g) = \exp(g \cdot x) g \exp(x)^{-1} g^{-1}$. The map $\phi_x : V_x \rightarrow G$ is a morphism of algebraic varieties over k .

Lemma 3. For $x \in \mathfrak{n}_J(\mathbb{F}_p)$, the map ϕ_x is defined over \mathbb{F}_p . That is, there exists an \mathbb{F}_p -morphism $(\phi_x)_{\mathbb{F}_p} : (V_x)_{\mathbb{F}_p} \rightarrow G_{\mathbb{F}_p}$ such that $\phi_x = (\phi_x)_{\mathbb{F}_p} \otimes_{\mathbb{F}_p} k$.

Proof. We first recall that \mathcal{N} has an \mathbb{F}_p -structure and the adjoint action $G \times \mathcal{N} \rightarrow \mathcal{N}$ is defined over \mathbb{F}_p . The restricted nullcone \mathcal{N}_1 is a subvariety of \mathcal{N} with \mathbb{F}_p -structure since the p -map $[p]$ is a morphism of algebraic varieties and defined over \mathbb{F}_p . Let $f_{\mathbb{F}_p}$ be the composition of $(V_x)_{\mathbb{F}_p} \xrightarrow{\psi_x} (\mathfrak{n}_J)_{\mathbb{F}_p} \xrightarrow{\exp} (U_J)_{\mathbb{F}_p}$ such that $g \mapsto g \cdot x \mapsto \exp(g \cdot x)$. Let $\iota_{\mathbb{F}_p}, h_{\mathbb{F}_p} : G_{\mathbb{F}_p} \rightarrow G_{\mathbb{F}_p}$ be the morphisms of varieties defined by $\iota_{\mathbb{F}_p}(g) = g^{-1}$ and $h_{\mathbb{F}_p}(g) = g \exp(x)^{-1}$ for all $g \in G$. Let $m_{\mathbb{F}_p} : G_{\mathbb{F}_p} \times G_{\mathbb{F}_p} \times G_{\mathbb{F}_p} \rightarrow G_{\mathbb{F}_p}$ and $\Delta_{\mathbb{F}_p} : G_{\mathbb{F}_p} \rightarrow G_{\mathbb{F}_p} \times G_{\mathbb{F}_p} \times G_{\mathbb{F}_p}$ be the product and diagonal morphisms respectively. Then the composition

$$\phi_{x, \mathbb{F}_p} = m_{\mathbb{F}_p} \circ (f_{\mathbb{F}_p} \times h_{\mathbb{F}_p} \times \iota_{\mathbb{F}_p}) \circ \Delta_{\mathbb{F}_p}$$

defines an \mathbb{F}_p -morphism $(V_x)_{\mathbb{F}_p} \rightarrow G_{\mathbb{F}_p}$ such that $(\phi_x)_{\mathbb{F}_p} \otimes_{\mathbb{F}_p} k = \phi_x$. \square

Proposition 5. *Let G be a simple algebraic group and suppose that p is good for G . Assume that \mathcal{N}_1 is normal.*

- (a) *For any $x \in \mathfrak{n}_J(\mathbb{F}_p)$, $\phi_x : V_x \rightarrow G$ is a constant morphism of algebraic varieties.*
- (b) *For any $x \in \mathfrak{n}_J(\mathbb{F}_p)$, the map $\exp : G \cdot x \rightarrow G$ defined by $g \cdot x \mapsto g \exp(x) g^{-1}$ is a G -equivariant morphism extending the morphism $\exp : (G \cdot x) \cap \mathfrak{n}_J \rightarrow G$.*
- (c) *The map $\exp : G \cdot x \rightarrow G \cdot \exp(x)$ is an isomorphism of G -orbits for every $x \in \mathfrak{n}_J$.*

Proof. (a) The morphism $(\phi_x)_{\mathbb{F}_p}$ is actually defined over the local ring $\mathbb{Z}_{(p)}$ from the construction of \exp in Section 2. It is known that over $\mathbb{Z}_{(p)}$, the corresponding morphism is constant. Thus ϕ_x is also a constant morphism (see Lemma 1).

(b) First consider the map $f_x : G \rightarrow G$ by $f_x(g) = g \exp(x) g^{-1}$. By Proposition 4(c), we have $\text{Stab}_G(x) = C_G(\exp(x))$ and f_x factors through $G \rightarrow G \cdot x \cong G / \text{Stab}_G(x)$ to get a morphism $\bar{f}_x : G \cdot x \rightarrow G$ by the universal property of the quotient varieties by a group action. We still need to show that $\bar{f}_x : (G \cdot x) \cap \mathfrak{n}_J \rightarrow G$ is the same as \exp when restricted to $G \cdot x \cap \mathfrak{n}_J$. If $x' \in \mathfrak{n}_J \cap G \cdot x$, then there exists $g \in V_x$ such that $g \cdot x = x' \in \mathfrak{n}_J$. By (a), we have $\phi_x(g) = 1$ in G , i.e.,

$$\bar{f}_x(x') = g \exp(x) g^{-1} = \exp(g \cdot x) = \exp(x').$$

Part (c) follows from Proposition 4(c). \square

2.9. We can now prove the main result of this section concerning the exponential map over the restricted nullcone.

Theorem 3. *Let G be a simple algebraic group such that $G_{sc} \rightarrow G$ is separable and let p be a good prime for G . Assume that \mathcal{N}_1 is normal. With J defined in Theorem 2 such that $\mathcal{N}_1 = G \cdot \mathfrak{n}_J$, then the isomorphism $\exp : \mathfrak{n}_J \rightarrow U_J$ extends uniquely to a G -equivariant isomorphism $\exp : \mathcal{N}_1 \rightarrow \mathcal{U}_1$ of algebraic varieties and has the following properties:*

- (a) *For any $0 \neq x \in \mathcal{N}_1$, the map \exp restricted to kx is a homomorphism of algebraic groups $\exp : kx \rightarrow U$ that can be extended to a good A_1 .*
- (b) *For any $x, y \in \mathcal{N}_1$, $[x, y] = 0$ if and only if $[\exp(x), \exp(y)] = 1$.*
- (c) *The isomorphism is defined over \mathbb{F}_p .*

For the rest of the paper, we call \exp the exponential map. The inverse map $\log : \mathcal{U}_1 \rightarrow \mathcal{N}_1$ is the logarithmic map.

Proof. First the isomorphism $\exp : \mathfrak{n}_J \rightarrow \mathcal{U}_J$ extending uniquely to $\exp : \mathcal{N}_1 \rightarrow \mathcal{U}_1$ was proved in Proposition 4.

To prove (a), we can assume that $0 \neq x \in \mathfrak{n}_J$. The map $\exp_x : G_a \rightarrow U_J$ ($t \mapsto \exp(tx)$) defines a homomorphism of algebraic groups which can be extended to a good A_1 using the argument of [Sei, Prop. 5.5]. We now use the argument of [Sei, Lem. 6.3] to see that $y \in C_{\mathfrak{g}}(x)$ if and only if $y \in C_{\mathfrak{g}}(\exp(x))$. For the same reason, we can assume that $y \in \mathfrak{n}_J$ and then, by [Sei, Prop. 6.1], we have $\exp(x) \in C_G(y) = C_G(\exp(y))$. Thus (b) follows.

For (c), the map $\exp : \mathfrak{n}_J \rightarrow \mathcal{U}_J$ is defined over \mathbb{F}_p . Thus its extension is also defined over \mathbb{F}_p since both \mathcal{N}_1 and \mathcal{U}_1 are defined over \mathbb{F}_p . \square

3. \mathbb{F}_p -EXPRESSIBILITY

3.1. In this section we assume that the prime p is good for the simple algebraic group G and that \mathcal{N}_1 is normal. Let $\exp : \mathcal{N}_1 \rightarrow \mathcal{U}_1$ be the exponential map and let $\log : \mathcal{U}_1 \rightarrow \mathcal{N}_1$ be the logarithmic map.

Definition 1. An element $x \in \mathfrak{g}$ is \mathbb{F}_p -expressible if $x = \sum_{i=1}^n c_i x_i$ where $c_i \in k$, $x_i \in \mathfrak{g}(\mathbb{F}_p)$, $x_i^{[p]} = 0$, and $[x_i, x_j] = 0$ for $1 \leq i, j \leq n$.

Let $\mathcal{N}^{\mathbb{F}_p}$ be the set of \mathbb{F}_p -expressible elements of \mathfrak{g} . From the definition given above we have $\mathcal{N}^{\mathbb{F}_p} \subseteq \mathcal{N}_1$. The adjoint action of the algebraic group G on the variety \mathcal{N}_1 induces an action of $G(\mathbb{F}_p)$ on the variety $\mathcal{N}^{\mathbb{F}_p}$.

We can also formulate an analogous notion of \mathbb{F}_p -expressibility for elements in G .

Definition 2. An element $g \in G$ is \mathbb{F}_p -expressible if

$$g = \exp(t_1 x_1) \exp(t_2 x_2) \dots \exp(t_n x_n)$$

where $t_i \in k$, $x_i \in \mathfrak{g}(\mathbb{F}_p)$, $x_i^{[p]} = 0$, and $[x_i, x_j] = 0$ for $1 \leq i, j \leq n$.

Let $\mathcal{U}^{\mathbb{F}_p}$ be the variety of \mathbb{F}_p -expressible elements of G . If $g \in \mathcal{U}^{\mathbb{F}_p}$, then $g^p = 1$, and so $\mathcal{U}^{\mathbb{F}_p} \subseteq \mathcal{U}$. Similarly, $G(\mathbb{F}_p)$ acts on $\mathcal{U}^{\mathbb{F}_p}$.

3.2. Let $\mathcal{N}_{[2]} = \{(x, y) \in \mathcal{N}_1 \times \mathcal{N}_1 : [x, y] = 0\}$. This is the restricted variety of commuting nilpotent elements in \mathfrak{g} . G acts on $\mathcal{N}_{[2]}$ via diagonal adjoint action and $\mathcal{N}_{[2]}$ is defined over \mathbb{F}_p . Let us formulate the following assumption on \mathfrak{g} .

Assumption 1. Let $J \subset \Delta$ be given as in Theorem 2 with $\mathcal{N}_1 = G \cdot \mathfrak{n}_J$. Assume that $\mathcal{N}_{[2]} = G \cdot ((\mathfrak{n}_J \times \mathfrak{n}_J) \cap \mathcal{N}_{[2]})$.

For $p \geq h$, we have $\mathfrak{n} = \mathfrak{n}_J$ and the assumption is true, because x, y generates a nilpotent Lie subalgebra, which is conjugated under G to an abelian subalgebra of \mathfrak{n} . It is interesting to note that in order to verify the assumption for smaller primes we may need new information about the computation for support varieties for the second Frobenius kernel of G . The support variety of the trivial module for G_2 in that case is $\mathcal{N}_{[2]}$.

We also note that $G \cdot ((\mathfrak{n}_J \times \mathfrak{n}_J) \cap \mathcal{N}_{[2]})$ is always a closed subvariety of $\mathcal{N}_{[2]}$. In fact,

$$Z = \{(gP_J, z) \in G/P_J \times \mathcal{N}_{[2]} \mid g \cdot z \in \mathfrak{n}_J \times \mathfrak{n}_J\}$$

is a closed subvariety of $G/P_J \times \mathcal{N}_{[2]}$ and $G \cdot (\mathfrak{n}_J \times \mathfrak{n}_J) \cap \mathcal{N}_{[2]}$ is the image of Z under the projection to the second component. Because G/P_J is a complete algebraic variety, it follows that $G \cdot (\mathfrak{n}_J \times \mathfrak{n}_J) \cap \mathcal{N}_{[2]}$ is closed in $\mathcal{N}_{[2]}$.

3.3. The two notions of \mathbb{F}_p -expressibility are related using the exponential map. This is shown in the following result.

Proposition 6. *Suppose that Assumption 1 is satisfied. Let $x_1, x_2, \dots, x_n \in \mathcal{N}_1$ such that $[x_i, x_j] = 0$ for all $i, j = 1, 2, \dots, n$.*

(a) *For any $t_1, t_2, \dots, t_n \in k$,*

$$(3.3.1) \quad \exp\left(\sum_{i=1}^n t_i x_i\right) = \prod_{i=1}^n \exp(t_i x_i).$$

(b) *An element g of G is \mathbb{F}_p -expressible if and only if $g = \exp(x)$ for some $x \in \mathcal{N}^{\mathbb{F}_p}$. Moreover, the map \exp maps $\mathcal{N}^{\mathbb{F}_p}$ onto $\mathcal{U}^{\mathbb{F}_p}$. In particular, for any element $1 \neq g \in G(\mathbb{F}_p)$ such that $g^p = 1$, then $g \in \mathcal{U}_1^{\mathbb{F}_p}$.*

Proof. (a) Since \mathcal{N}_1 is conical, we can use induction on n to reduce to proving $\exp(x + y) = \exp(x)\exp(y)$ for all $x, y \in \mathcal{N}_1$ such that $[x, y] = 0$. If there is $g \in G$ such that $g \cdot x$ and $g \cdot y$ are both in \mathfrak{n}_J , then we are done.

Define a map $f : \mathcal{N}_{[2]} \rightarrow G$ by

$$f(x, y) = \exp(x + y) \exp(-x) \exp(-y), \quad \text{for all } (x, y) \in \mathcal{N}_{[2]}.$$

Clearly f is a morphism of algebraic varieties and G -equivariant. By Proposition 2, $f(\mathcal{N}_{[2]} \cap (\mathfrak{n}_J \times \mathfrak{n}_J)) = 1$, where 1 is the identity element of the group G . Thus $f(G \cdot (\mathcal{N}_{[2]} \cap (\mathfrak{n}_J \times \mathfrak{n}_J))) = \{1\}$. By the assumption, we have $f(\mathcal{N}_{[2]}) = \{1\}$ and $\exp(x + y) = \exp(x)\exp(y)$ for all $x, y \in \mathcal{N}_1$ with $[x, y] = 0$. Part (b) is a direct consequence of part (a) since \exp is defined over \mathbb{F}_p . \square

3.4. We can now show that the exponential map sends \mathbb{F}_p -expressible elements in \mathfrak{g} to \mathbb{F}_p -expressible elements in G .

Theorem 4. *The G -equivariant isomorphism $\exp : \mathcal{N}_1 \rightarrow \mathcal{U}_1$ induces a $G(\mathbb{F}_p)$ -equivariant isomorphism $\exp : \mathcal{N}^{\mathbb{F}_p} \rightarrow \mathcal{U}^{\mathbb{F}_p}$ of varieties.*

Proof. Let $x = \sum_{i=1}^n c_i x_i \in \mathcal{N}^{\mathbb{F}_p}$. By Proposition 6, we then have $\exp(x) = \prod_{i=1}^n \exp(c_i x_i)$. Thus $\exp(\mathcal{N}^{\mathbb{F}_p}) \subseteq \mathcal{U}^{\mathbb{F}_p}$. Conversely, any

$$g = \exp(t_1 x_1) \exp(t_2 x_2) \cdots \exp(t_n x_n) = \exp\left(\sum_{i=1}^n t_i x_i\right) \in \exp(\mathcal{N}^{\mathbb{F}_p}).$$

\square

4. FINITE MORPHISMS OF SUPPORT VARIETIES

Unless otherwise stated, we will assume throughout this section that p is good, \mathcal{N}_1 is normal, and Assumption 1 is satisfied. In particular when $p \geq h$, these conditions are automatically satisfied.

4.1. For each $x \in \mathcal{N}_1$, we denote by $\hat{x} : G_a \rightarrow G$ the homomorphism of algebraic groups defined by $\hat{x}(t) = \exp(tx)$ (see Theorem 3).

Let E be an elementary abelian p -subgroup of $G(\mathbb{F}_p)$ of rank n . We may write $E = \langle y_1 \rangle \times \langle y_2 \rangle \times \cdots \times \langle y_n \rangle$ with independent generators y_1, y_2, \dots, y_n . From Proposition 6(b), there exist nilpotent elements of $\mathcal{N}^{\mathbb{F}_p}$, namely x_1, x_2, \dots, x_n such that $\hat{x}_i(1) = y_i$ for $i = 1, 2, \dots, n$. We can now define a map $\sigma : \mathbb{A}^n \rightarrow G$ of algebraic varieties by $\sigma(t_1, \dots, t_n) = \hat{x}_1(t_1)\hat{x}_2(t_2) \cdots \hat{x}_n(t_n)$. Since $y_i \in G(\mathbb{F}_p)$, we have $x_i \in \mathfrak{g}(\mathbb{F}_p)$. Set $\hat{E} = \sigma(\mathbb{A}^n)$.

Proposition 7. *The map σ is a homomorphism of algebraic groups with the following properties:*

- (a) $\sigma(\mathbb{A}^n)$ is an abelian algebraic subgroup of G ;
- (b) $\text{Im}(\sigma) \subseteq \mathcal{U}^{\mathbb{F}_p}$ and $\text{Im}(d\sigma) \subseteq \mathcal{N}^{\mathbb{F}_p}$;
- (c) $\sigma : \mathbb{A}^n \rightarrow \hat{E}$ is an isomorphism of algebraic varieties.

Proof. (a) It follows from Theorem 3(b) that $[x_i, x_j] = 0$. So Proposition 6 shows that σ is a homomorphism of algebraic groups and $\sigma(\mathbb{A}^n)$ is abelian.

(b) Since $\text{Im}(\sigma)$ is an abelian subgroup of G and $x_1, x_2, \dots, x_n \in \mathfrak{g}(\mathbb{F}_p)$, it follows that $\text{Im}(\sigma) \subseteq \mathcal{U}^{\mathbb{F}_p}$. Now consider the differential $d\sigma : \text{Lie}(\mathbb{A}^n) \rightarrow \text{Lie}(G)$ whose image is an abelian Lie subalgebra which is the k -linear span of the set x_1, x_2, \dots, x_n . Therefore, $\text{Im}(d\sigma) \subseteq \mathcal{N}^{\mathbb{F}_p}$.

(c) Suppose that $\ker(\sigma)$ has positive dimension. Then x_1, \dots, x_n would be linearly dependent over k . Since $x_i \in \mathfrak{g}(\mathbb{F}_p)$ for $1 \leq i \leq n$, the elements x_1, \dots, x_n would have to be linearly dependent over \mathbb{F}_p . Without loss of generality we may assume that x_1 is an \mathbb{F}_p -linear combination of x_2, \dots, x_n . This shows that $y_1 = y_2^{a_2} \cdots y_n^{a_n}$ for some integers a_2, \dots, a_n . This contradicts the fact that y_1, \dots, y_n are independent generators of E . Hence, $\mathbb{A}^n \rightarrow \sum_{i=1}^n kx_i$ is an isomorphism. Now the fact that σ is an isomorphism of varieties follows from the isomorphism $\exp : \sum_{i=1}^n kx_i \rightarrow \hat{E}$. \square

4.2. For a given elementary abelian p -group E , we set $J = \text{Rad}(kE)$, which is the ideal generated by $y - 1$ for all $y \in E$. Note that kE is the restricted enveloping algebra of the trivial restricted (abelian) Lie algebra (J/J^2) . The cohomological variety of kE can be identified with $|E|_k = J/J^2$ [FP2], which is a k -vector space.

Let $E = \langle y_1 \rangle \times \langle y_2 \rangle \times \cdots \times \langle y_n \rangle$ for an independent generating set $\{y_1, \dots, y_n\}$. Then $|E|_k$ can be identified with k^n by $(t_1, t_2, \dots, t_n) \mapsto \sum_{i=1}^n t_i(y_i - 1) + J^2$. Under the above identification, for $M \in \text{mod}(E)$, the support variety of M can be identified with [Ben1, 5.8.2, 5.8.3]

$$(4.2.1) \quad |E|_M = \{(t_1, t_2, \dots, t_n) : M \text{ is not free over } \langle 1 + \sum_{i=1}^n t_i(y_i - 1) \rangle\} \cup \{0\}.$$

We say that M is *projective over $\langle x \rangle$* or $M|_{\langle x \rangle}$ is *projective* if M is projective over the group algebra $k\langle x \rangle$ when x is an invertible element of order p in a group ring or over the restricted enveloping algebra of the 1-dimensional Lie algebra kx when x is an element of the restricted Lie algebra with $x^{[p]} = 0$.

For each $g \in G(\mathbb{F}_p)$, $gEg^{-1} = \langle gy_1g^{-1} \rangle \times \langle gy_2g^{-1} \rangle \times \cdots \times \langle gy_ng^{-1} \rangle$ is an elementary abelian p -subgroup of rank n . Let $E' = \langle u_1 \rangle \times \langle u_2 \rangle \times \cdots \times \langle u_m \rangle$ be another elementary abelian p -subgroup of $G(\mathbb{F}_p)$ such that $gE'g^{-1} \subseteq E$ for some $g \in G(\mathbb{F}_p)$. We write $gu_i g^{-1} = \prod_{j=1}^n y_j^{r_{ij}}$. Then the matrix (r_{ij}) has full rank over the field \mathbb{F}_p . For each $(t_1, \dots, t_n) \in |E|_k$ and $u = 1 + \sum_{i=1}^m t_i(u_i - 1) \in kE'$ we have that

$$(4.2.2) \quad gug^{-1} = 1 + \sum_{i=1}^m t_i(gu_i g^{-1} - 1) = 1 + \sum_{j=1}^n \left(\sum_{i=1}^m t_i r_{ij} \right) (y_j - 1) + r_2$$

where r_2 is an element in J^2 . To prove the relation above we use the identity $(yz-1) = (y-1) + (z-1) + (y-1)(z-1)$. The conjugation map by $g : E' \rightarrow E$ induces a map $\mathcal{S}(g) : |E'|_k \rightarrow |E|_k$. Under the given basis and the above identifications, the map $\mathcal{S}(g)$ is given by the matrix (r_{ij}) . Although the matrix description of the

map depends on the choice of bases for E' and E , the map $\mathcal{S}(g)$ is independent of the bases.

Let \mathcal{E} be the category whose objects are elementary abelian p -subgroups E of the finite group $G(\mathbb{F}_p)$ and the morphism sets are $(E, E') = \{g \in G(\mathbb{F}_p) : gEg^{-1} \subseteq E'\}$. Let $\mathcal{S} : \mathcal{E} \rightarrow \mathcal{V}$ be the functor that assigns to each E the cohomological variety of E where \mathcal{V} is the category of all algebraic k -varieties. The morphism $g : E \rightarrow E'$ induces a map $\mathcal{S}(g) : |E|_k \rightarrow |E'|_k$. Since the category \mathcal{E} has only finitely many objects, the direct limit of the functor \mathcal{S} exists in \mathcal{V} .

Let $|\widehat{G(\mathbb{F}_p)}|_k = \varinjlim_{\mathcal{E}} |E|_k$ be the direct limit with the maps $\rho_E : |E|_k \rightarrow \varinjlim_{\mathcal{E}} |E|_k$. This direct limit has the following universal property: if we are given an algebraic variety V and any collection of morphisms $\phi_E : |E|_k \rightarrow V$ of algebraic varieties such that for every morphism $g : E \rightarrow E'$ in \mathcal{E} we have the following commutative diagram,

$$\begin{array}{ccc} |E|_k & \xrightarrow{\mathcal{S}(g)} & |E'|_k \\ \phi_E \downarrow & & \downarrow \phi_{E'} \\ V & \xrightarrow{\text{Id}} & V, \end{array}$$

then there is a unique morphism of algebraic varieties $\psi : \varinjlim_{\mathcal{E}} |E|_k \rightarrow V$ that makes the following diagram commute:

$$\begin{array}{ccc} |E|_k & \xrightarrow{\rho_E} & \varinjlim_{\mathcal{E}} |E|_k \\ \phi_E \downarrow & & \downarrow \psi \\ V & \xrightarrow{\text{Id}} & V. \end{array}$$

Given $E = \langle y_1 \rangle \times \langle y_2 \rangle \times \cdots \times \langle y_n \rangle$ and $x_1, x_2, \dots, x_n \in \mathcal{N}^{\mathbb{F}_p}$ such that $\exp(x_i) = y_i$ for $i = 1, 2, \dots, n$, define $\hat{\zeta}_E : |E|_k \rightarrow G$ by

$$(4.2.3) \quad \hat{\zeta}_E(t_1, t_2, \dots, t_n) = \prod_{i=1}^n \exp(t_i x_i).$$

Now let $\zeta_E : |E|_k \rightarrow G/G(\mathbb{F}_p)$ be the map defined as $\hat{\zeta}_E$ composed with the quotient map $\pi : G \rightarrow G/G(\mathbb{F}_p)$. The above discussion together with Theorem 3 shows that the map ζ_E is independent of the choice of basis for E . It follows from Proposition 7 that ζ_E is a finite map onto its image.

Let $\log : \mathcal{U}_1 \rightarrow \mathcal{N}_1$ be the inverse morphism of \exp and $\overline{\log} : \mathcal{U}_1/G(\mathbb{F}_p) \rightarrow \mathcal{N}_1/G(\mathbb{F}_p)$ be the induced morphism (see Theorem 3).

Theorem 5. *Let G be a simple algebraic group and assume that p is good, \mathcal{N}_1 is normal, and the Assumption 1 is satisfied. There are finite surjective maps of varieties $\phi : |\widehat{G(\mathbb{F}_p)}|_k \rightarrow \mathcal{U}^{\mathbb{F}_p}/G(\mathbb{F}_p)$ and $\psi : |\widehat{G(\mathbb{F}_p)}|_k \rightarrow \mathcal{N}^{\mathbb{F}_p}/G(\mathbb{F}_p)$ such that $\psi = \overline{\log} \circ \phi$ and $\phi \circ \rho_E = \zeta_E$ for each elementary abelian subgroup E of $G(\mathbb{F}_p)$.*

Proof. The finite group $G(\mathbb{F}_p)$ acts on the algebraic group G by conjugation. Let $E = \langle y_1 \rangle \times \langle y_2 \rangle \times \cdots \times \langle y_n \rangle$ and $E' = \langle y'_1 \rangle \times \langle y'_2 \rangle \times \cdots \times \langle y'_m \rangle$ be elementary abelian p -subgroups of $G(\mathbb{F}_p)$ with $gE'g^{-1} \subseteq E$ for some $g \in G(\mathbb{F}_p)$. Let $y_i = \exp(x_i)$ for $i = 1, 2, \dots, n$ and $y'_j = \exp(x'_j)$ for $j = 1, 2, \dots, m$ where $x_i, x'_j \in \mathfrak{g}_{\mathbb{F}_p}$ for all i, j . Under the adjoint action of G on \mathfrak{g} , $\text{Ad}(g)(x'_i) = \sum_{j=1}^n r_{ij} x_j$. Then for each

$$(t_1, t_2, \dots, t_m) \in |E'|_k,$$

$$(4.2.4) \quad \begin{aligned} \pi(\hat{\zeta}_{E'}(t_1, \dots, t_m)) &= \pi(g \cdot \hat{\zeta}_{E'}(t_1, \dots, t_m)) = \pi(g(\prod_{i=1}^m \exp(t_i x'_i))g^{-1}) \\ &= \pi(\prod_{i=1}^n \exp(\sum_{j=1}^n t_i r_{ij} x_j)) = \zeta_E(\mathcal{S}(g)(t_1, t_2, \dots, t_m)). \end{aligned}$$

The above identity proves that the diagram

$$\begin{array}{ccc} |E'|_k & \xrightarrow{\mathcal{S}(g)} & |E|_k \\ \zeta_{E'} \downarrow & & \downarrow \zeta_E \\ G/G(\mathbb{F}_p) & \xrightarrow{\text{id}} & G/G(\mathbb{F}_p) \end{array}$$

commutes for all $g \in G(\mathbb{F}_p)$. The horizontal map on the bottom of the diagram is induced by the conjugation of g and thus is the identity map on $G/G(\mathbb{F}_p)$.

Hence, by the universal property of the direct limit, there exists a map $\phi : \varinjlim_E |E|_k \rightarrow G/G(\mathbb{F}_p)$. The image of each ζ_E is in $\mathcal{U}^{\mathbb{F}_p}$; thus $\phi : \varinjlim_E |E|_k \rightarrow \mathcal{U}^{\mathbb{F}_p}/G(\mathbb{F}_p)$ is defined. The map ϕ is onto since, for each $u \in \mathcal{U}^{\mathbb{F}_p}$, there exists an elementary abelian p -subgroup E such that $\hat{\zeta}_E(|E|_k)$ contains u . The map ϕ is finite because there are only finitely many elementary abelian p -subgroups and each ζ_E is finite. Since \log is a $G(\mathbb{F}_p)$ -isomorphism of $\mathcal{U}^{\mathbb{F}_p}$ with $\mathcal{N}^{\mathbb{F}_p}$, the map \log induces the isomorphism $\overline{\log}$ between the quotient spaces $\mathcal{U}^{\mathbb{F}_p}/G(\mathbb{F}_p)$ and $\mathcal{N}^{\mathbb{F}_p}/G(\mathbb{F}_p)$. We define $\psi = \overline{\log} \circ \phi$ with $\psi : |\widehat{G(\mathbb{F}_p)}|_k \rightarrow \mathcal{N}^{\mathbb{F}_p}/G(\mathbb{F}_p)$. The finiteness of ψ follows from the finiteness of ϕ . \square

We remark that, by Quillen's Stratification Theorem [Ben1, Cor 5.6.4], $|G(\mathbb{F}_p)|_k$ is homeomorphic to $|\widehat{G(\mathbb{F}_p)}|_k = \varinjlim_E |E|_k$. For the sake of convenience, we define our maps ϕ and ψ explicitly on $|\widehat{G(\mathbb{F}_p)}|_k$ rather than on $|G(\mathbb{F}_p)|_k$.

4.3. For $M \in \text{mod}(G(\mathbb{F}_p))$, let $|\widehat{G(\mathbb{F}_p)}|_M = \varinjlim_E |E|_M$. Observe that $|\widehat{G(\mathbb{F}_p)}|_M$ is a closed subvariety of $|\widehat{G(\mathbb{F}_p)}|_k$. By a well-known result of Avrunin and Scott [AS], the restriction maps induce an inseparable isogeny $\delta : |\widehat{G(\mathbb{F}_p)}|_M \rightarrow |G(\mathbb{F}_p)|_M$. A fundamental question is to describe the image of $|\widehat{G(\mathbb{F}_p)}|_M$ under the maps ϕ and ψ . We begin this investigation by proving a result which compares restrictions of nilpotent (and unipotent) elements on a rational G -module M .

Proposition 8. *Let M be a finite dimensional k -vector space and $x, y \in \text{End}_k(M)$ be two commuting elements such that $x \neq 0$ and $x^p = y^{p-1} = 0$. Then*

- (a) $1 + x$ and $1 + x + y$ are invertible, and
- (b) if M is a free module over the group algebra $k\langle 1 + x \rangle$, then M is free over the group algebra $k\langle 1 + x + y \rangle$.

Proof. Since $x^p = 0$ and $x \neq 0$, the element $1 + x$ is invertible of order p in $\text{End}_k(M)$. It is clear that $1 + x + y$ is invertible. There exists an isomorphism of algebras $k\langle 1 + x \rangle \cong k[T]/\langle T^p \rangle$ where $1 + x \mapsto 1 + T$. Since M is free as a module over $k\langle 1 + x \rangle$, M is free over $k[T]/\langle T^p \rangle$. Let $\{v_1, \dots, v_r\}$ be a free basis. Then $\{v_i, Tv_i, \dots, T^{p-1}v_i \mid i = 1, \dots, r\}$ is a k -basis of M . In particular $x^{p-1} \neq 0$.

Let \mathfrak{l} be a two dimensional trivial restricted Lie algebra with basis $\{z_1, z_2\}$. Define a restricted \mathfrak{l} -module structure on M by $z_1 \mapsto x$ and $z_2 \mapsto y$. Note that the support variety of M as an \mathfrak{l} -module [FP2] is

$$|M|_{\mathfrak{l}} = \{z \in \mathfrak{l} \mid M|_{\langle z \rangle} \text{ is not projective}\} \cup \{0\}.$$

Let $M = M_1 \oplus M_2 \oplus \cdots \oplus M_s$ be a decomposition of M into indecomposable $u(\mathfrak{l})$ -modules. Note that M is free over $\langle z \rangle$ if and only if M_j is free over $\langle z \rangle$ for all j . So without a loss of generality we may assume that M is indecomposable over $u(\mathfrak{l})$.

By our assumption $y^{p-1} = 0$, so the above characterization of the support variety of M shows that $z_2 \in |M|_{\mathfrak{l}}$ while $z_1 \notin |M|_{\mathfrak{l}}$. Consequently, $|M|_{\mathfrak{l}}$ is a proper closed subvariety of \mathfrak{l} . The projective variety $\text{Proj}(|M|_{\mathfrak{l}})$ is a proper closed connected subvariety of \mathbb{P}^1 [FP2] and is either empty or a single point. Hence, $|M|_{\mathfrak{l}}$ is at most a 1-dimensional vector subspace of \mathfrak{l} spanned by the line kz_1 . It follows that $z_1 + z_2 \notin |M|_{\mathfrak{l}}$ since $z_2 \in |M|_{\mathfrak{l}}$ and $z_1 \notin |M|_{\mathfrak{l}}$. Therefore, M is a projective module for the algebra $u(\langle z_1 + z_2 \rangle)$ and the proposition follows.¹ \square

4.4. Let $\sigma : \text{SL}_2 \rightarrow G$ be a homomorphism of algebraic groups defined over the localization $\mathbb{Z}_{(p)}$ of \mathbb{Z} at p . The differential $d\sigma : \text{Dist}(\text{SL}_2) \rightarrow \text{Dist}(G)$ is a homomorphism of associative algebras. Note that the distribution algebra of the unipotent subgroup $1 + kE_{21}$ of SL_2 has a basis $E_{21}^{(n)}$ satisfying $E_{21}^{(n)} E_{21}^{(m)} = \binom{n+m}{n} E_{21}^{(n+m)}$. Let $x \in \mathfrak{g}$ such that $x = d\sigma(E_{12})$. We set $x^{(n)} = d\sigma(E_{12}^{(n)}) \in \text{Dist}(G)$.

For any rational G -module M , the action of $\exp(tx)$ is the same as $\sum_{n \geq 0} t^n x^{(n)}$ by Proposition 2. Note that $x^{(n)} x^{(m)} = \binom{n+m}{n} x^{(n+m)}$ (see [St]). For $n = \sum_i r_i p^i$ with $0 \leq r_i < p$, we have that $x^{(n)} = \prod_i (x^{(p^i)})^{r_i} / r_i!$. Let $b_s = \sum_{i=0}^s r_i p^i$. By considering the images in $\text{End}_k(M)$, we have

$$(4.4.1) \quad \exp(tx) = \sum_{s \geq 0} \sum_{0 \leq r_0, \dots, r_s < p} \frac{x^{r_0} (x^{(p)})^{r_1} \cdots (x^{(p^s)})^{r_s}}{r_0! r_1! \cdots r_s!} t^{b_s}.$$

4.5. Let $x \in \mathcal{N}_1$. There is a homomorphism of $\sigma : \text{SL}_2 \rightarrow G$ such that $x = d\sigma(E_{21})$. As in Section 4.4, $x^{(n)} \in \text{Dist}(G)$ is defined with fixed σ . The following proposition will provide some motivation for the results in the following two subsections.

Proposition 9. *Let $M \in \text{mod}(G)$. Suppose x satisfies $(x^{(p^i)})^{p-1} = 0$ in $\text{End}_k(M)$ for all $i \geq 1$. Then for each $t \in k^*$, $M|_{\langle \exp(tx) \rangle}$ is free if and only if $M|_{\langle x \rangle}$ is free.*

Proof. Note that in $\text{End}_k(M)$ we can write $\exp(tx) = 1 + tx + y$ such that tx and y satisfy the condition of Proposition 8. Since $t \in k^*$, $M|_{\langle x \rangle}$ is free implies that $M|_{\langle 1+tx \rangle}$ is free. Therefore, by Proposition 8, $M|_{\langle \exp(tx) \rangle}$ is free. Conversely, we can substitute $tx + y$ for x and $-y$ for y in Proposition 8. Then the same argument shows that if $M|_{\langle \exp(tx) \rangle}$ is free, then $M|_{\langle x \rangle}$ is free. \square

When $G = \text{SL}_2$ and x is a positive root vector, the condition of the above proposition is satisfied for any G -module M all of whose weights are strictly less than $p(p-1)$. Therefore, under these conditions, M is projective over the Sylow p -subgroup of $\text{SL}_2(\mathbb{F}_p)$ if and only if it is projective over the nilpotent radical of the Borel subalgebra. Consequently, M is projective as an $\text{SL}_2(\mathbb{F}_p)$ -module if and only if

¹We thank Julia Pevtsova for pointing out a gap in the earlier proof of (b). The earlier version relied on the proof of [Ben2, p. 129, Lemma 2.25.5], which is not correct because the subgroup of upper triangular matrices in the centralizer contains a Sylow p -subgroup if and only if there is only one $p \times p$ Jordan block.

M is projective for the Lie algebra \mathfrak{sl}_2 . This result was proved in [LN, Thm. 4.3] for SL_2 by classifying all indecomposable SL_2 -modules with weights less than $p(p-1)$ and computing their dimensions. It turns out that the indecomposable SL_2 -modules with weights less than $p(p-1)$ and dimension divisible by p are projective over \mathfrak{sl}_2 . The aforementioned proposition provides a much more natural (and enlightening) proof of this result.

4.6. The category \mathcal{C}_p . Let G be a simple algebraic group of Lie rank l , and let \mathcal{C}_p be the full subcategory of G -modules for which all dominant weights λ satisfy the condition

$$(4.6.1) \quad \sum_{i=1}^l \sum_{j=1}^l \langle \lambda, \alpha_i^\vee \rangle b_{ij} < p(p-1)/2.$$

Here the matrix (b_{ij}) is the inverse matrix of the Cartan matrix $(\langle \alpha_i, \alpha_j^\vee \rangle)$. Let $\omega_1, \omega_2, \dots, \omega_l$ be the fundamental weights. Note that $\omega_i = \sum_{j=1}^l b_{ij} \alpha_j$, and

$$\omega_i^\vee = 2\omega_i / \langle \alpha_i, \alpha_i \rangle = \sum_{j=1}^l b_{ji} \alpha_j^\vee$$

satisfies the condition that $\lambda = \sum_{i=1}^l \langle \lambda, \omega_i^\vee \rangle \alpha_i$ for any $\lambda \in X(T)$. Hence the left hand side of (4.6.1) equals $\sum_{j=1}^l \langle \lambda, \omega_j^\vee \rangle$. For a simple algebraic group G let c be the value given in the table below.

type	A_l	B_l	C_l	D_l	E_6	E_7	E_8	F_4	G_2
c	$((l+1)/2)^2$	$l(l+1)/2$	$l^2/2$	$l(l-1)/2$	16	27	46	11	4

The condition $\langle \lambda, \alpha_0^\vee \rangle < p(p-1)/c$, where α_0 is the highest short root of the indecomposable root system, will insure that λ satisfies the condition (4.6.1). The computation of c is provided in the Appendix in §6.

Let $x \in \mathcal{N}^{\mathbb{F}_p}$. We have $x = t_1 x_1 + t_2 x_2 + \dots + t_n x_n$ where $x_i \in \mathfrak{g}(\mathbb{F}_p)$, and $[x_i, x_j] = 0$. Let $1 \leq i \leq n$ be fixed. According to [Sei], there exists a homomorphism $\sigma : \mathrm{SL}_2 \rightarrow G$ of algebraic groups such that $d\sigma(E_{12}) = x_i$ (cf. §2.6). Let T' be the maximal torus of SL_2 and T be the maximal torus in G . Since M is a G -module, we can conjugate x_i and assume that $x_i \in \mathfrak{n}_J$ and the image of T' is contained in T . Since $\mathrm{hom}(T', T) = \mathrm{hom}(G_m, T) = \mathrm{hom}_{\mathbb{Z}}(X(T), \mathbb{Z})$, the homomorphism $\sigma : T' \rightarrow T$ determines an element $t^\vee \in \mathrm{hom}_{\mathbb{Z}}(X(T), \mathbb{Z})$. On any G -module, T' acts on the weight space that has T -weight λ by the T' -weight $\langle \lambda, t^\vee \rangle = t^\vee(\lambda)$. By [C, Lemma 5.6.5], we can choose a Weyl group element conjugation to assume that $t^\vee(\alpha) \geq 0$ for all $\alpha \in \Phi^+$.

By Dynkin's theorem [C, Prop 5.6.6], the possible values for $a_j = t^\vee(\alpha_j)$ are 0, 1, 2. For any weight $\lambda \in X(T)$, write $\lambda = \sum_{j=1}^l \langle \lambda, \omega_j^\vee \rangle \alpha_j$. Consequently, for any dominant weight λ of the G -module M in \mathcal{C}_p , we have that

$$(4.6.2) \quad t^\vee(\lambda) = \sum_{j=1}^l \langle \lambda, \omega_j^\vee \rangle t^\vee(\alpha_j) \leq \sum_{j=1}^l 2 \langle \lambda, \omega_j^\vee \rangle < p(p-1).$$

Note that the above condition is equivalent to the statement that $t^\vee(w_0(\lambda)) > -p(p-1)$ where w_0 is the longest element of the Weyl group. Thus for any $M \in \mathcal{C}_p$ and any weight μ of M , there is a dominant weight λ of M in $W\mu$ such that $w_0(\lambda) \leq \mu \leq \lambda$ in the usual partial order. Since $t^\vee(\nu) \geq 0$ for all $\nu \in \mathbb{N}\Phi^+$, we have

$p(p-1) > t^\vee(\mu) > -p(p-1)$. Note that each $x^{(p^s)}$ has T' -weight $2p^s$. If $v \in M$ has T -weight μ , then $(x^{(p^s)})^{p-1}v \neq 0$ would have T' -weight $2(p-1)p^s + t^\vee(\mu) \geq p(p-1)$, assuming that $s > 0$. Thus, $(x^{(p^s)})^{p-1}v = 0$, and $(x^{(p^s)})^{p-1}M = 0$.

4.7. Let us fix some notation for the rest of this section. Let $x = t_1x_1 + t_2x_2 + \cdots + t_nx_n \in \mathcal{N}^{\mathbb{F}_p}$ where $x_1, \dots, x_n \in \mathfrak{g}(\mathbb{F}_p)$ and $t_1, \dots, t_n \in k$. Assume that $[x_i, x_j] = 0$ and $x_i^{[p]} = 0$. Set $u = \prod_{i=1}^n \exp(t_i x_i) \in \mathcal{U}^{\mathbb{F}_p}$ and $y = 1 + \sum_{i=1}^n t_i(y_i - 1) \in kG(\mathbb{F}_p)$ where $y_i = \exp(x_i)$ for $i = 1, 2, \dots, n$. Recall that under these conditions: $\phi(t_1, t_2, \dots, t_n) = u$ and $\psi(t_1, t_2, \dots, t_n) = x$.

Theorem 6. *Assume that G satisfies the conditions at the beginning of Section 4. Let $M \in \text{mod}(G)$ such that $(x_i^{(p^s)})^{p-1} = 0$ in $\text{End}_k M$ for all $s \geq 1$ (i.e. if M is in \mathcal{C}_p). Then the following three conditions are equivalent.*

- (a) $M|_{\langle x \rangle}$ is not free.
- (b) $M|_{\langle u \rangle}$ is not free.
- (c) $M|_{\langle y \rangle}$ is not free.

Proof. (a) \Leftrightarrow (c). First observe that as operators in $\text{End}_k(M)$,

$$(4.7.1) \quad y - 1 = \sum_{i=1}^n t_i x_i + \sum_{i=1}^n \sum_{j \geq 2} t_i x_i^{(j)} = x + \sum_{i=1}^n \sum_{j \geq 2} t_i x_i^{(j)}.$$

Since $x_i^{(j)}$ are all commuting elements in $\text{End}_k(M)$, the assumption shows that $(x_i^{(j)})^{p-1} = 0$ for all $j \geq 2$. Applying Proposition 8 repeatedly by adding the terms $t_i x_i^{(j)}$, we see that $M|_{\langle y \rangle}$ is free whenever $M|_{\langle x \rangle}$ is free. Conversely, assume that $M|_{\langle y \rangle}$ is free. Note that $(y - 1)^p = 0$ in $\text{End}_k(M)$. By adding $-t_i x_i^{(j)}$ for $j \geq 2$ we obtain that $M|_{\langle x \rangle}$ is free, from Proposition 8.

(a) \Leftrightarrow (b). An expansion of u as an operator in $\text{End}_k(M)$ has the form

$$(4.7.2) \quad u = 1 + x + \sum_{j_1, j_2, \dots, j_n} \prod_{i=1}^n t_i^{j_i} x_i^{(j_i)}.$$

The summation is over all $(j_1, j_2, \dots, j_n) \in \mathbb{N}^n$ such that $\sum_{i=1}^n j_i \geq 2$. Since all factors in (4.6.2) commute in $\text{End}_k(M)$, we have

$$(4.7.3) \quad \left(\prod_{i=1}^n t_i^{j_i} x_i^{(j_i)} \right)^{p-1} = 0$$

by the assumption. Then the same argument as above shows that $M|_{\langle x \rangle}$ is free if and only if $M|_{\langle u \rangle}$ is free. \square

4.8. We now apply Proposition 8 to describe the image of $|\widehat{G(\mathbb{F}_p)}|_M$ in $\mathcal{U}^{\mathbb{F}_p}/G(\mathbb{F}_p)$ (resp. $\mathcal{N}^{\mathbb{F}_p}/G(\mathbb{F}_p)$) under ϕ (resp. ψ).

Corollary 1. *Let G be a simple algebraic group such that p is good, \mathcal{N}_1 is normal, and Assumption 1 holds and let $M \in \mathcal{C}_p$. Then*

- (a) $\{u \in \mathcal{U}^{\mathbb{F}_p} : M|_{\langle u \rangle} \text{ is not free}\} = \exp(\{x \in \mathcal{N}^{\mathbb{F}_p} : M|_{\langle x \rangle} \text{ is not free}\})$.
- (b) $\phi(|\widehat{G(\mathbb{F}_p)}|_M) = \{u \in \mathcal{U}^{\mathbb{F}_p} : M|_{\langle u \rangle} \text{ is not free}\}/G(\mathbb{F}_p) \cup \{0\}$.
- (c) $\psi(|\widehat{G(\mathbb{F}_p)}|_M) = \{x \in \mathcal{N}^{\mathbb{F}_p} : x^{[p]} = 0, M|_{\langle x \rangle} \text{ is not free}\}/G(\mathbb{F}_p) \cup \{0\}$.

Proof. Part (a) follows directly from the equivalence of (a) and (b) in Theorem 6. Part (b) can be seen by using the equivalence of (b) and (c) of Theorem 6. Finally, part (c) holds because of (a) and (c) of Theorem 6. \square

4.9. A precise relationship between $|G(\mathbb{F}_p)|_M$ and $|G_1|_M$ can now be provided when M is a module in \mathcal{C}_p .

Corollary 2. *Let G be a simple algebraic group and assume that p satisfies the assumptions at the beginning of Section 4. If M is in \mathcal{C}_p , then $\psi(\widehat{|G(\mathbb{F}_p)|}_M) = (\mathcal{N}_1^{\mathbb{F}_p} \cap |\mathfrak{g}|_M)/G(\mathbb{F}_p)$. Furthermore,*

$$\dim |G(\mathbb{F}_p)|_M = \dim(\mathcal{N}_1^{\mathbb{F}_p} \cap |\mathfrak{g}|_M).$$

Proof. The first statement follows from Corollary 1(c), and the equality of dimensions holds because ψ is a finite map. \square

For M in \mathcal{C}_p , the preceding result provides a complete answer to the question (1.1.2) raised by Parshall. This relationship will be used in Section 5 to compute the complexity of modules for the finite group $G(\mathbb{F}_p)$. We should also add that for $M \in \text{mod}(G)$, $|\mathfrak{g}|_M$ is a closed G -invariant subvariety of \mathcal{N}_1 and thus the union of (finitely many) nilpotent orbits. An interesting and useful problem would be to determine the dimension of the intersection of a nilpotent orbit with $\mathcal{N}_1^{\mathbb{F}_p}$.

5. APPLICATIONS

5.1. Alperin and Mason [AM2] proved that for a finite group $G(\mathbb{F}_q)$ with underlying root system of type A , D or E , a simple module S is isomorphic to the Steinberg module if and only if S is projective upon restriction to a root subgroup $X_\alpha(t)$. Our first application extends this result to all root systems in the case when $q = p$ and $p \geq h$.

Theorem 7. *Let G be a simple algebraic group with $p \geq h$. Then a simple module S for $G(\mathbb{F}_p)$ is the Steinberg module if and only if $S|_{X_\alpha(t)}$ is projective for some long root α .*

Proof. If S is the Steinberg module, then it is projective over $G(\mathbb{F}_p)$ and thus projective over all root subgroups.

On the other hand, suppose that $S|_{X_\alpha(t)}$ is projective for some long root α . Since all long roots are conjugate via the Weyl group action, we may assume that $\alpha = -\tilde{\alpha}$, where $\tilde{\alpha}$ is the highest root. Let $S = L(\lambda)$ where $\lambda \in X_1(T)$. Since $p \geq h$, for all weights μ of $L(\lambda)$ we have

$$\langle \mu, \tilde{\alpha}^\vee \rangle \leq \langle \lambda, \alpha_0^\vee \rangle \leq \langle (p-1)\rho, \alpha_0^\vee \rangle < p(p-1),$$

where α_0 is the highest short root. Now one can use a weight argument to show that $(x_\alpha^{(p^s)})^{p-1}$ acts as zero on S for $s \geq 1$ (since $\mu = w_0(\lambda + (p-1)p^s\alpha)$ is not a weight of $L(\lambda)$). It follows by Proposition 4.5 that S must be projective over $\langle x_\alpha \rangle$, and projective over G_1 by [FP2, (2.4)(b) Prop.]. This proves the conclusion because the only simple projective module over G_1 is the Steinberg module. \square

5.2. Janiszczak and Jantzen [JJ] proved that there are no periodic nonprojective simple modules for a group $G(\mathbb{F}_q)$ when $\text{rank}(G) \geq 2$. The following results demonstrate how the map ψ and the geometry of nilpotent orbits can be used to extend this result in several different directions because all simple $G(\mathbb{F}_p)$ -modules are in \mathcal{C}_p .

Proposition 10. *Let $G = \text{GL}_{n+1}(k)$ (Φ of type A_n). Then $\dim(\overline{\mathcal{O}} \cap \mathcal{N}^{\mathbb{F}_p}) \geq n$ for any nonzero nilpotent orbit \mathcal{O} . Furthermore, if G is simple of rank at least two and if \mathcal{O} is the minimal nilpotent orbit, then $\dim(\overline{\mathcal{O}} \cap \mathcal{N}^{\mathbb{F}_p}) \geq 2$.*

Proof. We first assume that G is of type A_n . Then every nilpotent orbit is a Richardson orbit [Hum4, 5.5]. The minimal orbit corresponds to a maximal parabolic subalgebra which has a nilpotent radical, that is, an n -dimensional abelian subalgebra with a basis consisting of root vectors in $\mathfrak{g}(\mathbb{F}_p)$. This shows that $\dim(\overline{\mathcal{O}} \cap \mathcal{N}^{\mathbb{F}_p}) \geq n$.

Note that for another simple algebraic group G of any type other than C_n ($n \geq 2$), G contains a rank 2 subgroup K defined over \mathbb{F}_p with root system A_2 consisting of some long roots of G . The minimal orbit of G is the orbit of a long root vector. Thus $\mathcal{O} \cap K$ contains the minimal nilpotent orbit of K . Note that $\text{Lie}(K_{\mathbb{F}_p}) \subseteq \mathfrak{g}_{\mathbb{F}_p}$. Thus the lemma follows from the result for type A_2 . For type C_n , it suffices to consider the case when $n = 2$ and then apply the same reasoning as above. In this case $C_2 = B_2$. Let α, β be the simple roots with β a long root. A quick computation shows that $\exp(x_\alpha)(x_\beta) = x_\beta + x_{\beta+\alpha} + x_{\beta+2\alpha} \in \mathcal{O}$. Now the actions of the maximal tori of the two type A_1 subgroups corresponding to the long roots β and $\beta + 2\alpha$ yield that $t^2x_\beta + tsx_{\beta+\alpha} + s^2x_{\beta+2\alpha} \in \mathcal{O}$ for all $t, s \in k^*$. Note that the set of all these elements is in $\mathcal{N}^{\mathbb{F}_p}$ and is a two dimensional closed subvariety in $kx_\beta + kx_{\beta+\alpha} + kx_{\beta+2\alpha} \subseteq \mathcal{N}^{\mathbb{F}_p}$. This proves the result for groups of type C_n . \square

Corollary 3. *Let G be a simple algebraic group and let $M \in \mathcal{C}_p$ be a G -module which is not projective as a $G(\mathbb{F}_p)$ -module.*

- (a) *If M is indecomposable in $\text{mod}(G(\mathbb{F}_p))$ and $\text{rank}(G) \geq 2$, then $\dim |G(\mathbb{F}_p)|_M \geq 2$.*
- (b) *If G has an underlying root system of type A_n , then $\dim |G(\mathbb{F}_p)|_M \geq n$.*

Proof. For (a), suppose that M is a nonprojective indecomposable module over $G(\mathbb{F}_p)$. Then M is nonprojective over \mathfrak{g} by [LN, Cor. 3.5]. Therefore, $G \cdot x_\beta \subseteq |\mathfrak{g}|_M$ for β the highest long root vector. Now the result follows from Proposition 10 and Corollary 2. Part (b) is a direct consequence of Proposition 10. \square

It is interesting to note that for simple algebraic groups with root systems other than of type A_n , the minimal orbit is rigid [CM, Lem. 7.1.5], and thus cannot be Richardson.

5.3. Rank 2 groups. For $\lambda \in X(T)$, let $\Phi_\lambda = \{\alpha \in \Phi^+ : \langle \lambda + \rho, \alpha^\vee \rangle \in p\mathbb{Z}\}$. When p is good, there exists a subset J of simple roots and $w \in W$ such that $w(\Phi_\lambda) = \Phi_J$. Let \mathfrak{u}_J be the nilpotent radical of the parabolic algebra determined by J . In [NPV, (6.6.1) Cor.] the support varieties of simple modules for \mathfrak{g} were calculated for rank 2 groups. The next result shows how to use this information to calculate the dimensions of the support varieties for simple modules over $G(\mathbb{F}_p)$ when G has rank two.

Theorem 8. *Let G be a simple algebraic group of rank 2 with underlying root system A_2 (resp. B_2 or G_2) with $p > 3$ (resp. $p > 7$, or $p > 19$) and let $\lambda \in X_1(T)$.*

- (a) *If $\lambda = (p-1)\rho$, then $\dim |G(\mathbb{F}_p)|_{L(\lambda)} = 0$.*
- (b) *If $\lambda \neq (p-1)\rho$, then $\dim |G(\mathbb{F}_p)|_{L(\lambda)} = \begin{cases} 2 & \text{for } A_2, \\ 3 & \text{for } B_2 \text{ and } G_2. \end{cases}$*

Proof. (a) Observe that $\lambda = (p-1)\rho$ if and only if $\Phi_\lambda = \Phi$. Furthermore, $L((p-1)\rho)$ is the Steinberg module which is projective over $G(\mathbb{F}_p)$; thus $|G(\mathbb{F}_p)|_{L(\lambda)} = \{0\}$.

(b) We may now assume that Φ_λ is a subroot system of Φ which is empty or of type A_1 . Let $J = \{\alpha\}$ be the set consisting of one simple root. By [NPV, 6.6.1], we have that $G \cdot \mathfrak{u}_J \subseteq |\mathfrak{g}|_{L(\lambda)}$. Note that \mathfrak{u}_J is the nilpotent radical of a minimal parabolic subalgebra P_α . By a result of Steinberg [Hum4, Lemma 5.8 (i)], we have $G \cdot \mathfrak{u}_{\{\alpha\}} = G \cdot \mathfrak{u}_{\{\beta\}}$ for any simple root β since G is simple. Thus we can choose the simple root α such that \mathfrak{u}_J contains a sufficiently large abelian subalgebra defined over \mathbb{F}_p . For type A_2 , \mathfrak{u}_J is abelian of dimension 2, which is also the p -rank of the group $G(\mathbb{F}_p)$. For the types B_2 and G_2 , we can choose α to be the short simple root. Then \mathfrak{u}_α contains a three dimensional abelian subalgebra (a sum of three commuting root spaces). Note that $G(\mathbb{F}_p)$ has p -rank 3 for both B_2 and G_2 (for $p > 3$). If $J = \emptyset$, then \mathfrak{u}_J is the unipotent radical of a Borel subalgebra. An elementary abelian p -subgroup of maximal rank is contained in the Borel subgroup which gives an abelian Lie subalgebra of $\mathfrak{g}(\mathbb{F}_p)$ (see Proposition 7). Thus $\dim |G(\mathbb{F}_p)|_{H^0(\lambda)}$ is the p -rank of the group $G(\mathbb{F}_p)$. \square

We refer the reader to [GLR, Table 3.3.1] for a list of p -ranks of finite simple groups of Lie type.

5.4. Induced modules. In [NPV, (6.2.1) Thm.], it was shown that for p good and $\lambda \in X(T)_+$, if $J \subset \Pi$ with $w(\Phi_\lambda) = \Phi_J$, then $|\mathfrak{g}|_{H^0(\lambda)} = G \cdot \mathfrak{u}_J$. The theorem below allows us to use this computation to determine the dimension of support varieties for $H^0(\lambda)$ over $G(\mathbb{F}_p)$. The ease of these computations illustrates the power of this geometric approach.

Theorem 9. *Let G be a connected reductive algebraic group with p good for G . Suppose $\lambda \in X(T)_+$ such that $\langle \lambda, \alpha_0^\vee \rangle < p(p-1)/c$.*

- (a) *If J' is a subset of the simple roots such that $\mathfrak{u}_{J'}$ is abelian and $\mathfrak{u}_{J'} \subseteq |\mathfrak{g}|_{H^0(\lambda)}$, then*

$$\dim_k \mathfrak{u}_{J'} \leq \dim |G(\mathbb{F}_p)|_{H^0(\lambda)} \leq \min\{p\text{-rank } G(\mathbb{F}_p), \frac{1}{2} \dim |\mathfrak{g}|_{H^0(\lambda)}\}.$$

- (b) *If $w(\Phi_\lambda) = \Phi_J$ for some $w \in W$ and \mathfrak{u}_J is abelian, then $\dim_k |G(\mathbb{F}_p)|_{H^0(\lambda)} = \dim_k \mathfrak{u}_J$.*

- (c) *If $\Phi_\lambda = \emptyset$, then $\dim |G(\mathbb{F}_p)|_{H^0(\lambda)} = \dim |G(\mathbb{F}_p)|_k$.*

Proof. The assumption on λ insures that $H^0(\lambda)$ is in \mathcal{C}_p . (a) Suppose that $\mathfrak{u}_{J'} \subseteq |\mathfrak{g}|_{H^0(\lambda)}$ where $\mathfrak{u}_{J'}$ is abelian. Then $\mathfrak{u}_{J'} \subseteq \mathcal{N}^{\mathbb{F}_p} \cap |\mathfrak{g}|_{H^0(\lambda)} \subseteq \psi(|G(\mathbb{F}_p)|_{H^0(\lambda)})$. Hence, $\dim_k \mathfrak{u}_{J'} \leq \dim |G(\mathbb{F}_p)|_{H^0(\lambda)}$. The other inequality follows by [LN, Thm. 3.4(b)] and the fact that the dimension of the support variety of a module is always bounded by the dimension of the support variety of the trivial module which is precisely the p -rank of the group.

(b) Under the hypotheses we have $|\mathfrak{g}|_{H^0(\lambda)} = G \cdot \mathbf{u}_J$ where \mathbf{u}_J is abelian. Therefore by part (a), $\dim_k \mathbf{u}_J \leq \dim |G(\mathbb{F}_p)|_{H^0(\lambda)}$. On the other hand, by [LN, Thm. 3.4(b)], we have

$$\dim |G(\mathbb{F}_p)|_{H^0(\lambda)} \leq \frac{1}{2} \dim |\mathfrak{g}|_{H^0(\lambda)} = \dim_k \mathbf{u}_J.$$

The last equality uses the dimension formula (see [C, 5.10.2] and [Hum4, 6.7]).

(c) When $\Phi_\lambda = \emptyset$, then the elementary abelian p -subgroup of $G(\mathbb{F}_p)$ contained in the unipotent radical of the Borel subgroup B corresponds to an abelian subalgebra of $\mathfrak{g}_{\mathbb{F}_p}$ which is contained in \mathbf{u}_J and which has dimension equal to the p -rank of the finite group (see Proposition 7). \square

5.5. Computations for GL_n . We now concentrate on the group $G = \mathrm{GL}_n$ with underlying root system of type A_{n-1} . The p -rank of $\mathrm{GL}_n(\mathbb{F}_p)$ is given for $n \leq 7$ in the table below.

group	p -rank
$\mathrm{GL}_2(\mathbb{F}_p)$	1
$\mathrm{GL}_3(\mathbb{F}_p)$	2
$\mathrm{GL}_4(\mathbb{F}_p)$	4
$\mathrm{GL}_5(\mathbb{F}_p)$	6
$\mathrm{GL}_6(\mathbb{F}_p)$	9
$\mathrm{GL}_7(\mathbb{F}_p)$	12

By using Theorem 9, the dimensions of the support varieties for the induced modules $H^0(\lambda)$ with $\lambda \in X_1(T)$ can be computed completely for $n \leq 5$. They can also be computed in all but two cases for $n = 6$ and $n = 7$. These computations are given in the tables below. In the two exceptional cases, the unipotent radical corresponding to the stabilizer Φ_λ is not abelian and an elementary abelian p -subgroup of largest rank is not contained in the unipotent radical.

$\mathrm{GL}_2(\mathbb{F}_p)$

6. APPENDIX

6.1. For a dominant integral weight $\lambda \in X(T)_+$, we express $\lambda = \sum_{i=1}^l \lambda_i \omega_i$ in terms of the fundamental weights $\omega_1, \omega_2, \dots, \omega_l$. We give an estimate for $t^\vee(\omega_i)$ for each root system using the table in [Hum1, 13.2] and the fact that $0 \leq t^\vee(\alpha_i) \leq 2$ (see Corollary 1).

In this appendix we list all $a_i = t^\vee(\omega_i) = \sum_{j=1}^l 2b_{ij}$ for $t^\vee(\alpha_i) = 2$. Hence, a_i is twice the sum of the coefficients of ω_i when expressed in terms of simple roots. Set $n_i = \langle \omega_i, \alpha_0^\vee \rangle$ and $b_i = a_i/n_i$. Then $\langle \lambda, \alpha_0^\vee \rangle = \sum_{i=1}^l n_i \lambda_i$ and $t^\vee(\lambda) \leq \sum_{i=1}^l b_i n_i \lambda_i \leq c \langle \lambda, \alpha_0^\vee \rangle$, where $c = \max_i \{b_i\}$. The Coxeter number h is given by the formula $h = 1 + \sum_{i=1}^l n_i$.

Type	(n_1, \dots, n_l)	h	c
A_l	$(1, 1, \dots, 1)$	$l+1$	$((l+1)/2)^2$
B_l	$(2, 2, \dots, 2, 1)$	$2l$	$l(l+1)/2$
C_l	$(1, 2, \dots, 2)$	$2l$	$l^2/2$
D_l	$(1, 2, \dots, 2, 1, 1)$	$2l-2$	$l(l-1)/2$
E_6	$(1, 2, 2, 3, 2, 1)$	12	16
E_7	$(2, 2, 3, 4, 3, 2, 1)$	18	27

F_4	$(2, 4, 3, 2)$	12	11
G_2	$(2, 3)$	6	4

6.2. The quantity a_i is given below for all indecomposable root systems.

Type A. For $i = 1, 2, \dots, l$,

$$(6.2.1) \quad a_i = \frac{2}{l+1} \left[(l-i+1) \sum_{j=1}^i j + i \sum_{j=i+1}^l (l-j+1) \right] = i(l-i+1),$$

$$(6.2.2) \quad c = (l+1)^2/4.$$

Type B. For $i = 1, 2, \dots, l-1$,

$$(6.2.3) \quad a_i = \sum_{j=1}^i 2j + i \sum_{j=i+1}^l 2 = i(2l-i+1) \leq l(l+1),$$

$$(6.2.4) \quad a_l = \frac{1}{2} \sum_{j=1}^l 2j = l(l+1)/2,$$

$$(6.2.5) \quad c = l(l+1)/2.$$

Type C. For $i = 1, 2, \dots, l-1$,

$$(6.2.6) \quad a_i = \sum_{j=1}^{i-1} 2j + i(2 + \dots + 2 + 1) = i(2l-i),$$

$$(6.2.7) \quad c = \begin{cases} l^2/2 & \text{if } l > 3, \\ 5 & \text{if } l = 3. \end{cases}$$

Type D. For $i = 1, 2, \dots, l-2$,

$$(6.2.8) \quad a_i = \sum_{j=1}^i 2j + i(2 + \dots + 2 + 1 + 1) = i(2l-3-i),$$

$$(6.2.9) \quad a_{l-1} = a_l \leq (1 + 2 + \dots + (l-2)) + 2l-2 = l(l-1)/2,$$

$$(6.2.10) \quad c = l(l-1)/2 \quad (l \geq 4).$$
