FRACTAL RANDOM SERIES GENERATED BY POISSON-VORONOI TESSELLATIONS

PIERRE CALKA AND YANN DEMICHEL

ABSTRACT. In this paper, we construct a new family of random series defined on $\mathbb{R}^D$, indexed by one scaling parameter and two Hurst-like exponents. The model is close to Takagi-Knopp functions, save for the fact that the underlying partitions of $\mathbb{R}^D$ are not the usual dyadic meshes but random Voronoi tessellations generated by Poisson point processes. This approach leads us to a continuous function whose random graph is shown to be fractal with explicit and equal box and Hausdorff dimensions. The proof of this main result is based on several new distributional properties of the Poisson-Voronoi tessellation on the one hand, and an estimate of the oscillations of the function coupled with an application of a Frostman-type lemma on the other hand. Finally, we introduce two related models and provide in particular a box-dimension calculation for a derived deterministic Takagi-Knopp series with hexagonal bases.

INTRODUCTION

The original Weierstrass series (see [40]) is a fundamental example of a continuous but nowhere differentiable function. Among the more general family of Weierstrass-type functions, the Takagi-Knopp series can be defined in one dimension as

$$(1) \quad K_H(x) = \sum_{n=0}^{\infty} 2^{-nH} \Delta(2^n x), \quad x \in \mathbb{R},$$

where $\Delta(x) = \text{dist}(x, \mathbb{Z})$ is the sawtooth—or pyramidal—function and $H \in (0, 1]$ is called the Hurst parameter of the function. Introduced at the early beginning of the 20th century (see [22, 36]), they have been extensively studied since then (see the two recent surveys [2, 24]).

The construction of K_H is only based on two ingredients: a sequence of partitions of $\mathbb{R}$ (the dyadic meshes) associated with a decreasing sequence of amplitudes for the consecutive layers of pyramids. Therefore, we can easily extend definition (1) to dimension $D \geq 2$ using the D -dimensional dyadic meshes.

In order to provide realistic models for highly irregular signals such as rough surfaces (see [12, 15, 29] and Chapter 6 in [34]), it is necessary to randomize such

Key words and phrases. Poisson-Voronoi tessellation, Poisson point process, random functions, Takagi series, fractal dimension, Hausdorff dimension.

This work was partially supported by the French ANR grant PRESAGE (ANR-11-BS02-003), the French ANR grant MATAIM (ANR-09-BLAN-0029-01) and the French research group GeoSto (CNRS-GDR3477).

deterministic functions. Two common ways to do this are the following: either the pyramids are translated at each step by a random vector (see e.g. [11, 16, 38]), or the height of each pyramid is randomly chosen (see in particular [15] for the famous construction of the Brownian bridge).

In many cases the graphs of such functions are fractal sets. Therefore, their fractal dimensions provide crucial information for describing the roughness of the data (see [20, 26]). The two most common fractal dimensions are the box-dimension and the Hausdorff dimension. The former is in general easier to calculate whereas the latter is known only in very special cases (see e.g. [4, 9, 19, 25, 28]).

In this paper, a new family of Takagi-Knopp type series is introduced. Contrary to the previous randomization procedures, our key idea is to substitute a sequence of random partitions of $\mathbb{R}^D$ for the dyadic meshes. An alternative idea would have been to keep the cubes and choose independently and uniformly in each cube each center of a pyramid. Notably because the mesh has only D directions, it would be very tricky to calculate the Hausdorff dimension. One advantage for applicational purposes may be to get rid of the rigid structure induced by the cubes and to provide more flexibility with the irregular pattern. A classical model of a random partition is the Poisson-Voronoi tessellation.

For a locally finite set of points called nuclei, we construct the associated Voronoi partition of $\mathbb{R}^D$ by associating to each nucleus c its cell $\mathcal{C}_c$, i.e. the set of points which are closer to c than to any other nucleus. When the set of nuclei is a homogeneous Poisson point process, we speak of a Poisson-Voronoi tessellation (see e.g. [7, 30, 32]). In particular, the Poisson point process (resp. the tessellation) is invariant under any measure preserving transformation of $\mathbb{R}^D$, in particular any isometric transformation (see (2)). Moreover the cells from the tessellation are almost surely convex polytopes. Classical results for the typical Poisson-Voronoi cell include limit theorems (see [1]), distributional (see [5, 6]) and asymptotic results (see [8, 18]). The model is commonly used in various domains such as molecular biology (see [33]), thermal conductivity (see [23]) or telecommunications (see e.g. [39] and Chapter 5 in [3], Volume 1). The only parameter needed to describe the tessellation is the intensity $\lambda > 0$, i.e. the mean number of nuclei or cells per unit volume. In particular, the mean area of a typical cell from the tessellation is λ^{-1} . Multiplied by the scaling factor $\lambda^{\frac{1}{D}}$, the Poisson-Voronoi tessellation of intensity λ is equal in distribution to the Poisson-Voronoi tessellation of intensity one. This scaling invariance is a crucial property that will be widely used in the sequel.

Let $\lambda > 1$ and $\alpha, \beta > 0$. The parameter λ is roughly speaking a scaling factor and α, β are Hurst-like exponents. For every integer $n \geq 0$, we denote by $\mathcal{X}_n$ a homogeneous Poisson point process of intensity $\lambda^{n\beta}$ in $\mathbb{R}^D$ and by $\mathcal{T}_n = \{\mathcal{C}_c : c \in \mathcal{X}_n\}$ the set of cells of the underlying Poisson-Voronoi tessellation. We recall that $\lambda^{\frac{n\beta}{D}} \mathcal{T}_n \stackrel{\text{def}}{=} \{\lambda^{\frac{n\beta}{D}} \mathcal{C}_c : c \in \mathcal{X}_n\}$ is distributed as $\mathcal{T}_0$ and $\lambda^{\frac{\beta}{D}} \mathcal{T}_n \stackrel{\text{law}}{=} \mathcal{T}_{n-1}$ thanks to the scaling invariance. Moreover, for any isometric transformation $I : \mathbb{R}^D \rightarrow \mathbb{R}^D$, we have

$$(2) \quad I(\mathcal{T}_0) \stackrel{\text{def}}{=} \{I(\mathcal{C}_c) : c \in \mathcal{X}_0\} \stackrel{\text{law}}{=} \{\mathcal{C}_c : c \in \mathcal{X}_0\}.$$

Let $\Delta_n : \mathbb{R}^D \rightarrow [0, 1]$ be the random pyramidal function satisfying $\Delta_n = 0$ on $\bigcup_{c \in \mathcal{X}_n} \partial \mathcal{C}_c$, $\Delta_n = 1$ on $\mathcal{X}_n$ and piecewise linear (see Figure 1 and the beginning of section 1.2 for more details).

FIGURE 1. Construction of the elementary piecewise linear function Δ_n .

In the sequel the Poisson point processes $\mathcal{X}_n$ are assumed to be independent. We consider the continuous function

$$(3) \quad F_{\lambda, \alpha, \beta}(x) = \sum_{n=0}^{\infty} \lambda^{-\frac{n\alpha}{\beta}} \Delta_n(x), \quad x \in \mathbb{R}^D.$$

In particular $F_{\lambda, \alpha, \beta}$ is a sum of independent functions.

Let us denote by $\dim_B(K)$ and $\dim_H(K)$ the (upper) box-dimension and the Hausdorff dimension of a non-empty compact set K (see e.g. [14] for precise definitions). We are mainly interested in the exact values of these dimensions. Our result is the following:

Theorem 1. *Let $\lambda > 1$ and $0 < \alpha \leq \beta \leq 1$. Then $F_{\lambda, \alpha, \beta}$ is a continuous function whose random graph*

$$\Gamma_{\lambda, \alpha, \beta} = \{(x, F_{\lambda, \alpha, \beta}(x)) : x \in [0, 1]^D\} \subset \mathbb{R}^D \times \mathbb{R}$$

is a fractal set satisfying almost surely

$$(4) \quad \dim_B(\Gamma_{\lambda, \alpha, \beta}) = \dim_H(\Gamma_{\lambda, \alpha, \beta}) = D + 1 - \frac{\alpha}{\beta}.$$

Equalities (4) imply that the smaller $\frac{\alpha}{\beta}$ is, the more irregular $F_{\lambda, \alpha, \beta}$ and $\Gamma_{\lambda, \alpha, \beta}$ are (see Figure 2 and Figure 3). The result of Theorem 1 naturally holds when $[0, 1]^D$ is replaced with any cube of $\mathbb{R}^D$.

The paper is organized as follows. In the first section we state some preliminary results related to the geometry of the Poisson-Voronoi tessellations. We introduce in particular the oscillation sets $\mathcal{O}_{n, N}$ (see (7)) that are used to derive explicit distributional properties on the increments of Δ_n and precise estimates on the increments of $F_{\lambda, \alpha, \beta}$. Section 2 is then devoted to the proof of Theorem 1. An upper bound for $\dim_B(\Gamma_{\lambda, \alpha, \beta})$ comes from the estimation of the oscillations of $F_{\lambda, \alpha, \beta}$ whereas a lower bound for $\dim_H(\Gamma_{\lambda, \alpha, \beta})$ is obtained via a Frostman-type lemma. Finally, we introduce and study in the last section two related models: a deterministic series based on a hexagonal mesh and a random series based on a perturbation of the dyadic mesh.

In the sequel we will drop the indices λ , α and β so that $F = F_{\lambda, \alpha, \beta}$ and $\Gamma = \Gamma_{\lambda, \alpha, \beta}$.

FIGURE 2. Graph of the random function $F_{\lambda, \alpha, \beta}$ when $D = 1$. FIGURE 3. Graph of the random function $F_{\lambda, \alpha, \beta}$ when $D = 2$.

1. PRELIMINARY RESULTS

1.1. Notation. We consider the metric space $\mathbb{R}^D$, $D \geq 1$, endowed with the Euclidean norm $\|\cdot\|$. The closed ball with center $x \in \mathbb{R}^D$ and radius $r > 0$ is denoted by $B_r(x)$. We write $\text{Vol}(A)$ for the Lebesgue measure of a Borel set $A \subset \mathbb{R}^D$. In particular $\kappa_D = \text{Vol}(B_1(0))$. The unit sphere of $\mathbb{R}^D$ is denoted by $\mathbb{S}^{D-1}$ and σ_{D-1} will be the unnormalized area measure on $\mathbb{S}^{D-1}$. The surface area of $\mathbb{S}^{D-1}$ is then $\omega_{D-1} = \sigma_{D-1}(\mathbb{S}^{D-1})$. Finally, for all $s \geq 0$, the s -dimensional Hausdorff measure is $\mathcal{H}^s$.

For all $x, y \in [0, 1]^D$ and all $n \geq 0$ let

$$(5) \quad Z_n(x, y) = \lambda^{-\frac{n\alpha}{D}} (\Delta_n(x) - \Delta_n(y))$$

so that $F(x) - F(y) = \sum_{n=0}^{\infty} Z_n(x, y)$, and

$$(6) \quad S_n(x, y) = \sum_{\substack{m=0 \\ m \neq n}}^{\infty} Z_m(x, y)$$

so that $F(x) - F(y) = Z_n(x, y) + S_n(x, y)$. Notice that $Z_n(x, y)$ and $Z_m(x, y)$ are two independent random variables for $m \neq n$. In particular $Z_n(x, y)$ and $S_n(x, y)$ are independent.

Finally, we fix $H > \beta$. For all $n \geq 0$, we set $\tau_n = \lambda^{-\frac{nH}{D}}$.

1.2. Random oscillation sets. Remember that the function Δ_n is piecewise linear. Any maximal set on which Δ_n is linear is the convex hull $\text{Conv}(\{c\} \cup f)$ of the union of a nucleus c from $\mathcal{X}_n$ and a hyperface (i.e. a $(D-1)$ -dimensional face) f of the cell associated with c . The set $\mathcal{S}_n$ of such simplices tessellates $\mathbb{R}^D$. For all $n, N \geq 0$ we define the random sets

$$(7) \quad \mathcal{O}_{n,N} = \{x \in [0, 1]^D : \text{all points of } B_{\tau_N}(x) \text{ are in the same simplex of } \mathcal{S}_n \text{ as } x\}$$

and

$$(8) \quad W_N = \bigcap_{n=N}^{\infty} \mathcal{O}_{n,n}.$$

The set $\mathcal{O}_{n,N}$ is referenced as a random oscillation set because the oscillations of the function Δ_n can be properly estimated only on such set.

The first result states that these sets are not too ‘small’.

Proposition 1.1.

- (i) *There exists a constant $C > 0$ such that, for all $x \in [0, 1]^D$ and all $N \geq n \geq 0$,*

$$\mathbb{P}(x \notin \mathcal{O}_{n,N}) \leq C \lambda^{\frac{n\beta - NH}{D}}.$$

- (ii) *We have $\lim_{N \rightarrow \infty} \mathbb{P}(\text{Vol}(W_N) > 0) = 1$.*

Proof. (i) By invariance by translation of $\mathcal{X}_n$ and $\mathcal{T}_n$, we notice that for every $x \in \mathbb{R}^D$,

$$(9) \quad \mathbb{P}(0 \notin \mathcal{O}_{n,N}) = \mathbb{P}(x \notin \mathcal{O}_{n,N}).$$

Let Sk_n be the skeleton of the simplex tessellation $\mathcal{S}_n$, i.e. the union of the boundaries of all simplices (see the grey region on Figure 4).

In particular, we have the equivalence

$$(10) \quad x \notin \mathcal{O}_{n,N} \iff x \in \text{Sk}_n + B_{\tau_N}(0).$$

Let U be a uniform point in $[0, 1]^D$, independent of the tessellation $\mathcal{T}_n$, and let $\mathbb{P}_{\mathcal{X}_n}$ be the distribution of the Poisson point process $\mathcal{X}_n$. Using (9) and Fubini’s theorem, we get

$$\mathbb{P}(U \notin \mathcal{O}_{n,N}) = \int_{[0,1]^D} \mathbb{P}_{\mathcal{X}_n}(x \notin \mathcal{O}_{n,N}) dx = \mathbb{P}(0 \notin \mathcal{O}_{n,N}).$$

Moreover, the equivalence (10) implies that

$$(11) \quad \begin{aligned} \mathbb{P}(0 \notin \mathcal{O}_{n,N}) &= \mathbb{E}_{\mathcal{X}_n} \left(\int_{[0,1]^D} \mathbb{1}_{\text{Sk}_n + B_{\tau_N}(0)}(x) dx \right) \\ &= \mathbb{E}_{\mathcal{X}_n} (\text{Vol}((\text{Sk}_n + B_{\tau_N}(0)) \cap [0, 1]^D)). \end{aligned}$$

FIGURE 4. The skeleton of the complete tessellation (in grey).

It remains to calculate the Lebesgue measure of the set $(\text{Sk}_n + B_{\tau_N}(0)) \cap [0, 1]^D$. Denoting by $\mathcal{F}_n(a)$ the set of hyperfaces of the simplex tessellation $\mathcal{S}_n$ which intersect $[0, a]^D$ we have

$$\text{Vol}((\text{Sk}_n + B_{\tau_N}(0)) \cap [0, 1]^D) \leq \sum_{f \in \mathcal{F}_n(1)} \text{Vol}(f + B_{\tau_N}(0)) + \text{Vol}(\partial([0, 1]^D) + B_{\tau_N}(0)).$$

By the Steiner formula (see e.g. Prolog in [35]), we have for every $f \in \mathcal{F}_n(1)$,

$$\text{Vol}(f + B_{\tau_N}(0)) = \sum_{i=0}^{D-1} \lambda^{-\frac{NH(D-i)}{D}} \kappa_{D-i} V_i(f)$$

where $V_i(f)$ is the i -th intrinsic volume of f .

Consequently, we have

$$\begin{aligned} \mathbb{E}_{\mathcal{X}_n}(\text{Vol}((\text{Sk}_n + B_{\tau_N}(0)) \cap [0, 1]^D)) \\ (12) \quad \leq \sum_{i=0}^{D-1} \lambda^{-\frac{NH(D-i)}{D}} \kappa_{D-i} \mathbb{E}_{\mathcal{X}_n} \left(\sum_{f \in \mathcal{F}_n(1)} V_i(f) \right) + 4D \lambda^{-\frac{NH}{D}}. \end{aligned}$$

Using the invariance of $\mathcal{X}_n$ by scaling transformations and translations and the fact that V_i is a homogeneous function of degree i , we observe that for every $0 \leq i \leq D-1$,

$$\begin{aligned} \mathbb{E}_{\mathcal{X}_n} \left(\sum_{f \in \mathcal{F}_n(1)} V_i(f) \right) &= \lambda^{-\frac{n\beta i}{D}} \mathbb{E} \left(\sum_{f \in \mathcal{F}_0(\lambda^{\frac{n\beta}{D}})} V_i(f) \right) \\ (13) \quad &= \lambda^{-\frac{n\beta i}{D}} \mathbb{E} \left(\sum_{f \in \mathcal{F}_0(1)} V_i(f) \right) (\lambda^{\frac{n\beta}{D}})^D. \end{aligned}$$

Combining (11), (12) and (13), we obtain the required result (i).

(ii) The point (i) implies that

$$\mathbb{E}(\text{Vol}([0, 1]^D \setminus \mathcal{O}_{n,n})) = \int_{[0,1]^D} \mathbb{P}(x \notin \mathcal{O}_{n,n}) dx = \mathbb{P}(0 \notin \mathcal{O}_{n,n}) = O(\lambda^{\frac{n(\beta-H)}{D}}).$$

Therefore, we obtain

$$\mathbb{E}(\text{Vol}([0, 1]^D \setminus W_N)) \leq \sum_{n=N}^{\infty} \mathbb{E}(\text{Vol}([0, 1]^D \setminus \mathcal{O}_{n,n})) \leq \sum_{n=N}^{\infty} O(\lambda^{\frac{n(\beta-H)}{D}}) = O(\lambda^{\frac{N(\beta-H)}{D}}).$$

Finally, using Markov's inequality,

$$\begin{aligned} \mathbb{P}(\text{Vol}(W_N) < 1/2) &= \mathbb{P}(\text{Vol}([0, 1]^D \setminus W_N) \geq 1/2) \\ &\leq 2\mathbb{E}(\text{Vol}([0, 1]^D \setminus W_N)) \leq O(\lambda^{\frac{N(\beta-H)}{D}}) \end{aligned}$$

and the result (ii) follows. $\square$

1.3. Distribution of the random variable $Z_n(x, y)$. This subsection is devoted to the calculation of the distribution of $Z_n(x, y)$ conditionally on $\{x \in \mathcal{O}_{n,n}\}$ when $\|x - y\| \leq \tau_n$. In particular, we obtain in Proposition 1.2 below an explicit formula and an upper-bound for the conditional density of $Z_n(x, y)$. A similar method provides in Proposition 1.3 the integrability of the local Lipschitz constant of Z_0 . All these results will play a major role in the estimation of the oscillations of F (see Proposition 1.4) and the application of the Frostman criterion (see Proposition 1.5).

For any $x \in [0, 1]^D$, let $c_n(x)$ (resp. $\mathcal{C}_n(x)$) be the nucleus (resp. the cell) from the Voronoi tessellation $\mathcal{T}_n$ associated with x , i.e. the point of χ_n which is the closest to x (resp. the cell of such point). Let $c'_n(x)$ be the 'secondary nucleus' of x , i.e. the point of $\mathcal{X}_n$ which is the nucleus of the neighboring cell of $\mathcal{C}_n(x)$ in the direction of the half-line $[c_n(x), x)$. Moreover, for any $z_1 \neq z_2 \in \mathbb{R}^D$ and $x \in \mathbb{R}^D \setminus (B_{\tau_n}(z_1) \cup B_{\tau_n}(z_2))$, we consider

- the bisecting hyperplane H_{z_1, z_2} of $[z_1, z_2]$,
- the cone $\Lambda(z_1, x)$ of apex z_1 and generated by the ball $B_{\tau_n}(x)$,
- the set $A_{n,x}$ of couples (z_1, z_2) with $z_1 \notin B_{\tau_n}(x)$ such that x is between the hyperplane orthogonal to $z_2 - z_1$ and containing z_1 and the parallel hyperplane which is at distance τ_n from H_{z_1, z_2} on the z_1 -side:

$$\begin{aligned} A_{n,x} = \left\{ (z_1, z_2) \in B_{\tau_n}(x)^c \times \mathbb{R}^D : 0 \leq \langle x - z_1, z_2 - z_1 \rangle \right. \\ \left. \leq \frac{1}{2} \|z_2 - z_1\|^2 \left(1 - \frac{2\tau_n}{\|z_2 - z_1\|} \right) \right\}. \end{aligned}$$

Finally, we denote by $\mathcal{V}_n(x, z_1, z_2)$ the volume of the Voronoi flower associated with the intersection $H_{z_1, z_2} \cap \Lambda(z_1, x)$:

$$\mathcal{V}_n(x, z_1, z_2) = \text{Vol} \left(\bigcup \{ B_{\|u-z_1\|}(u) : u \in H_{z_1, z_2} \cap \Lambda(z_1, x) \} \right).$$

Proposition 1.2. *Let $n \geq 0$ and $x, y \in [0, 1]^D$ such that $x \in \mathcal{O}_{n,n}$ and $0 < \|x - y\| \leq \tau_n$. Then*

(i) *The increment $Z_n(x, y)$ is given by*

$$(14) \quad Z_n(x, y) = -\frac{2\lambda^{-\frac{n\alpha}{D}}}{\|c'_n(x) - c_n(x)\|^2} \langle x - y, c'_n(x) - c_n(x) \rangle.$$

FIGURE 5. The configuration of (z_1, z_2) with the associated Voronoi flower.

- (ii) The density g_{Z_n} of $Z_n(x, y)$ conditionally on $\{x \in \mathcal{O}_{n,n}\}$ is given by (22) for $D \geq 2$ and by (21) for $D = 1$. Moreover, it satisfies

$$(15) \quad \sup_{t \in \mathbb{R}} g_{Z_n}(t) \leq \frac{C}{\mathbb{P}(x \in \mathcal{O}_{n,n})} \|x - y\|^{-1} \lambda^{-\frac{n(\beta - \alpha)}{D}}$$

where C is a positive constant depending only on the dimension D .

Proof. (i) If $x \in \mathcal{O}_{n,n}$ and $\|x - y\| \leq \tau_n$, then

$$\Delta_n(x) = \frac{\text{dist}(x, H_{c_n(x), c'_n(x)})}{\text{dist}(c_n(x), H_{c_n(x), c'_n(x)})}.$$

Moreover,

$$\text{dist}(x, H_{c_n(x), c'_n(x)}) = \left\langle x - \frac{c_n(x) + c'_n(x)}{2}, \frac{c_n(x) - c'_n(x)}{\|c_n(x) - c'_n(x)\|} \right\rangle$$

and

$$\text{dist}(c_n(x), H_{c_n(x), c'_n(x)}) = \frac{1}{2} \|c_n(x) - c'_n(x)\|.$$

It remains to use the definition (5) of $Z_n(x, y)$ to obtain the result (i).

(ii) We need to determine the joint distribution of $(c_n(x), c'_n(x))$. We notice that x belongs to $\mathcal{O}_{n,n}$ if and only if all the points of $B_{\tau_n}(x)$ have the same nucleus as x in $\mathcal{X}_n$ and the same ‘secondary nucleus’. In other words,

$$x \in \mathcal{O}_{n,n} \iff \Lambda(c_n(x), x) \cap H_{c_n(x), c'_n(x)} \subset \mathcal{C}_{c_n(x)} \cap \mathcal{C}_{c'_n(x)}.$$

 FIGURE 6. The random variable $Z_n(x, y)$.

By Mecke-Slivnyak's formula (see Corollary 3.2.3 in [35]), for any measurable and non-negative function $h : \mathbb{R}^2 \rightarrow \mathbb{R}_+$ we have

$$\begin{aligned} & \mathbb{E}(h(c_n(x), c'_n(x)) \mathbb{I}_{\{x \in \mathcal{O}_{n,n}\}}) \\ &= \mathbb{E} \left(\sum_{z_1 \neq z_2} h(z_1, z_2) \mathbb{I}_{(c_n(x), c'_n(x))}(z_1, z_2) \mathbb{I}_{\{x \in \mathcal{O}_{n,n}\}} \right) \\ &= \lambda^{2n\beta} \iint h(z_1, z_2) \mathbb{P}(\Lambda(z_1, x) \cap H_{z_1, z_2} \subset \mathcal{C}_{z_1} \cap \mathcal{C}_{z_2}) \mathbb{I}_{A_{n,x}}(z_1, z_2) dz_1 dz_2 \\ &= \lambda^{2n\beta} \iint h(z_1, z_2) \exp(-\lambda^{n\beta} \mathcal{V}_n(x, z_1, z_2)) \mathbb{I}_{A_{n,x}}(z_1, z_2) dz_1 dz_2. \end{aligned}$$

We point out a small abuse of notation above: the sets $\mathcal{C}_{z_1}$ and $\mathcal{C}_{z_2}$ are Voronoi cells associated with z_1 and z_2 when the underlying set of nuclei is $\mathcal{X}_n \cup \{z_1, z_2\}$. We proceed now with the change of variables $z_2 = (z_2)_{\rho, u} = z_1 + \rho u$ with $\rho > 0$ and $u \in \mathbb{S}^{D-1}$.

Let $L_n(x) = \|c'_n(x) - c_n(x)\|$, $u_n(x) = \frac{c'_n(x) - c_n(x)}{L_n(x)}$ and $\mathcal{V}'_n(\cdot) = \mathcal{V}_n(x, z_1, z_1 + \cdot)$ (keep in mind that $\mathcal{V}'_n$ will still depend on x and z_1 though this dependency will not be visible for the sake of readability). The density of $(L_n(x), u_n(x))$ conditionally on $\{x \in \mathcal{O}_{n,n}\}$ with respect to the product measure $d\rho d\sigma_{D-1}(u)$ is

$$(16) \quad \frac{\lambda^{2n\beta}}{\mathbb{P}(x \in \mathcal{O}_{n,n})} \int_{B_{\tau_n}(x)^c} \exp(-\lambda^{n\beta} \mathcal{V}'_n(\rho u)) \mathbb{I}_{[0, \frac{\rho}{2} - \tau_n]}(\langle x - z_1, u \rangle) \rho^{D-1} dz_1.$$

Using (14), we can rewrite the quantity $Z_n(x, y)$ as a function of $L_n(x)$ and $u_n(x)$ as

$$Z_n(x, y) = -\frac{2\lambda^{-\frac{n\alpha}{D}}}{L_n(x)} \langle x - y, u_n(x) \rangle.$$

The density of the distribution of $Z_n(x, y)$ conditionally on $\{x \in \mathcal{O}_{n,n}\}$ can then be calculated in the following way: for any non-negative measurable function $\psi : \mathbb{R}_+ \rightarrow \mathbb{R}_+$,

$$(17) \quad \mathbb{E}(\psi(Z_n(x, y))) = \frac{\lambda^{2n\beta}}{\mathbb{P}(x \in \mathcal{O}_{n,n})} \int_{B_{\tau_n}(x)^c} J_n(x, y, z_1, \rho, u) dz_1$$

where $J_n(x, y, z_1, \rho, u)$ is equal to

$$\iint \psi(-2\lambda^{-\frac{n\alpha}{D}} \rho^{-1} \langle x - y, u \rangle) e^{-\lambda^{n\beta} \mathcal{V}'_n(\rho u)} \mathbb{I}_{\mathbb{R}_+}(\langle x - z_1, u \rangle) \rho^{D-1} d\rho d\sigma_{D-1}(u),$$

the domain of integration for ρ being $[2\tau_n + 2\langle x - z_1, u \rangle, \infty)$.

Case $D = 1$. We observe that $u = \pm 1$ and $\langle x - z_1, u \rangle = (x - z_1)u = \pm(x - z_1)$. Moreover, the condition $z_1 \notin B_{\tau_n}(x)$ means that $z_1 < x - \tau_n$ or $z_1 > x + \tau_n$. It implies that if $u = 1$ (resp. $u = -1$), the range of z_1 is $(-\infty, x - \tau_n)$ (resp. $(x + \tau_n, \infty)$) while for fixed z_1 the range of ρ is $(2\tau_n + 2(x - z_1), \infty)$ (resp. $(2\tau_n + 2(z_1 - x), \infty)$). Finally, the set $\bigcup \{B_{\|u - z_1\|}(u) : u \in H_{z_1, z_2} \cap \Lambda(z_1, x)\}$ is $[z_1, z_1 + \rho]$ (if $u = 1$) or $[z_1 - \rho, z_1]$ (if $u = -1$) so $\mathcal{V}'_n(\rho u) = \rho$ in both cases. Consequently, we have

$$(18) \quad \mathbb{E}(\psi(Z_n(x, y))) = \frac{\lambda^{2n\beta}}{\mathbb{P}(x \in \mathcal{O}_{n,n})} (I_1 + I_2)$$

where

$$I_1 = \int_{-\infty}^{x - \tau_n} \left(\int_{2\tau_n + 2(x - z_1)}^{+\infty} \psi(-2\lambda^{-n\alpha} \rho^{-1}(x - y)) e^{-\lambda^{n\beta} \rho} d\rho \right) dz_1$$

and

$$I_2 = \int_{x + \tau_n}^{+\infty} \left(\int_{2\tau_n + 2(z_1 - x)}^{+\infty} \psi(2\lambda^{-n\alpha} \rho^{-1}(x - y)) e^{-\lambda^{n\beta} \rho} d\rho \right) dz_1.$$

Applying Fubini's theorem in I_1 and then the change of variables $\rho' = -\rho$, we get

$$\begin{aligned} I_1 &= \int_{4\tau_n}^{+\infty} \psi(-2\lambda^{-n\alpha} \rho^{-1}(x - y)) e^{-\lambda^{n\beta} \rho} \left(\int_{x - \frac{\rho}{2} + \tau_n}^{x - \tau_n} dz_1 \right) d\rho \\ &= \int_{4\tau_n}^{+\infty} \psi(-2\lambda^{-n\alpha} \rho^{-1}(x - y)) e^{-\lambda^{n\beta} \rho} \left(\frac{\rho}{2} - 2\tau_n \right) d\rho \\ (19) \quad &= \int_{-\infty}^{-4\tau_n} \psi(2\lambda^{-n\alpha} \rho'^{-1}(x - y)) e^{-\lambda^{n\beta} |\rho'|} \left(\frac{|\rho'|}{2} - 2\tau_n \right) d\rho'. \end{aligned}$$

Applying Fubini's theorem in I_2 , we obtain

$$\begin{aligned} I_2 &= \int_{4\tau_n}^{+\infty} \psi(2\lambda^{-n\alpha} \rho^{-1}(x - y)) e^{-\lambda^{n\beta} \rho} \left(\int_{x + \tau_n}^{x + \frac{\rho}{2} - \tau_n} dz_1 \right) d\rho \\ (20) \quad &= \int_{4\tau_n}^{+\infty} \psi(2\lambda^{-n\alpha} \rho^{-1}(x - y)) e^{-\lambda^{n\beta} \rho} \left(\frac{\rho}{2} - 2\tau_n \right) d\rho. \end{aligned}$$

Combining (18), (19) and (20), we get

$$\mathbb{E}(\psi(Z_n(x, y))) = \frac{\lambda^{2n\beta}}{\mathbb{P}(x \in \mathcal{O}_{n,n})} \int_{|\rho| > 4\tau_n} \psi(2\lambda^{-n\alpha} \rho^{-1}(x - y)) e^{-\lambda^{n\beta} |\rho|} \left(\frac{|\rho|}{2} - 2\tau_n \right) d\rho.$$

Applying the change of variables $\rho = \rho_t = 2\lambda^{-n\alpha}t^{-1}(x-y)$, we get that the density of $Z_n(x, y)$ is, for $|t| < \lambda^{-n\alpha} \frac{|x-y|}{2\tau_n}$,

$$(21) \quad g_{Z_n}(t) = \frac{2\lambda^{2n\beta}}{\mathbb{P}(x \in \mathcal{O}_{n,n})} e^{-2\lambda^{n(\beta-\alpha)} \frac{|x-y|}{|t|}} \left(\lambda^{-n\alpha} \frac{|x-y|}{|t|} - 2\tau_n \right) \lambda^{-n\alpha} \frac{|x-y|}{t^2}.$$

In particular,

$$g_{Z_n}(t) \leq \frac{2\lambda^{2n\beta}}{\mathbb{P}(x \in \mathcal{O}_{n,n})} \frac{\lambda^{-3n\beta+n\alpha}}{|x-y|} \sup_{r>0} (e^{-2r} r^3),$$

which shows (15).

Case $D \geq 2$. We go back to (17). For almost any $u \in \mathbb{S}^{D-1}$, there exists a unique $v \in \mathbb{S}^{D-1} \cap \{y-x\}^\perp$ and a unique $s = \langle u, \frac{y-x}{\|y-x\|} \rangle \in (-1, 1)$ such that

$$u = u_{s,v} = s \frac{y-x}{\|y-x\|} + \sqrt{1-s^2} v.$$

In particular, we can rewrite the uniform measure of $\mathbb{S}^{D-1}$ as

$$d\sigma_{D-1}(u) = (1-s^2)^{\frac{D-3}{2}} ds d\sigma_{D-2}(v).$$

We thus get that $J_n(x, y, z_1, \rho, u)$ is also equal to

$$\begin{aligned} & \iiint \psi(2\lambda^{-\frac{n\alpha}{D}} \|x-y\| s \rho^{-1}) e^{-\lambda^{n\beta} \mathcal{V}'_n(\rho u_{s,v})} \\ & \quad \times \mathbb{I}_{\mathbb{R}_+}(\langle x-y, u_{s,v} \rangle) \rho^{D-1} (1-s^2)^{\frac{D-3}{2}} d\rho ds d\sigma_{D-2}(v), \end{aligned}$$

the domain of integration for ρ being $[2\tau_n + 2\langle x-z_1, u_{s,v} \rangle, \infty)$.

We now proceed with the change of variables $\rho = \rho_t = 2\lambda^{-\frac{n\alpha}{D}} \|x-y\| s t^{-1}$ with $st > 0$. We then deduce that the density $g_{Z_n}(t)$ at point t of $Z_n(x, y)$ conditionally on $\{x \in \mathcal{O}_{n,n}\}$ is given by

$$(22) \quad g_{Z_n}(t) = \frac{\lambda^{2n\beta}}{\mathbb{P}(x \in \mathcal{O}_{n,n})} \iiint J'_n(x, y, z_1, t, s, v) \mathbb{I}_{D_n}(x, y, z_1, t, s, v) ds d\sigma_{D-2}(v) dz_1$$

where

$$J'_n(x, y, z_1, t, s, v) = e^{-\lambda^{n\beta} \mathcal{V}'_n\left(\frac{2\lambda^{-\frac{n\alpha}{D}} \|x-y\| s u_{s,v}}{t}\right)} \left(\frac{2\lambda^{-\frac{n\alpha}{D}} \|x-y\| s}{t} \right)^D \frac{(1-s^2)^{\frac{D-3}{2}}}{t}$$

and

$$D_n = \left\{ (x, y, z_1, t, s, v) : \|x-z_1\| > \tau_n \text{ and } 0 \leq \langle x-z_1, u_{s,v} \rangle \leq \frac{\lambda^{-\frac{n\alpha}{D}} \|x-y\| s}{t} - \tau_n \right\}.$$

In the sequel, we only deal with the case $t > 0$ but the same could be done likewise for $t < 0$. We denote by x' the intersection of the half-line $[z_1, x)$ with the boundary of the Voronoi cell of z_1 . Moreover, we write $z_1 = x - \gamma w$ where $\gamma > \tau_n$ and $w \in \mathbb{S}^{D-1}$. In particular, we notice that

$$\|x' - z_1\| = \frac{\rho}{2\langle w, u_{s,v} \rangle} = \frac{\lambda^{-\frac{n\alpha}{D}} \|x-y\| s}{t\langle w, u_{s,v} \rangle}.$$

We can now easily estimate the volume $\mathcal{V}'_n(\cdot)$ in the following way:

$$(23) \quad \mathcal{V}'_n(\cdot) \geq \text{Vol}(B_{\|x'-z_1\|}(x')) = \kappa_D \left(\frac{\lambda^{-\frac{n\alpha}{D}} \|x-y\| s}{t\langle w, u_{s,v} \rangle} \right)^D.$$

We then proceed with the following change of variables: for almost any $w \in \mathbb{S}^{D-1}$, there exist a unique $\xi = \langle w, u_{s,v} \rangle \in [0, 1)$ and a unique $\eta \in \mathbb{S}^{D-1} \cap \{u_{s,v}\}^\perp$ such that $w = w_{\xi,\eta} = \xi u_{s,v} + \sqrt{1 - \xi^2} \eta$ and

$$(24) \quad dz_1 = \gamma^{D-1} d\gamma d\sigma_{D-1}(w) = \gamma^{D-1} (1 - \xi^2)^{\frac{D-3}{2}} d\gamma d\xi d\sigma_{D-2}(\eta).$$

In particular, when $(x, y, z_1, t, s, v) \in D_n$, we have

$$(25) \quad 0 \leq \gamma = \frac{\langle x - z_1, u_{s,v} \rangle}{\xi} \leq \frac{\lambda^{-\frac{n\alpha}{D}} \|x - y\| s}{t\xi}.$$

Consequently, for fixed $s, \xi \in (0, 1)$, we have

$$(26) \quad \iiint \mathbb{I}_{D_n} \gamma^{D-1} d\gamma d\sigma_{D-2}(v) d\sigma_{D-2}(\eta) \leq \frac{\omega_{D-2}^2}{D} \left(\frac{\lambda^{-\frac{n\alpha}{D}} \|x - y\| s}{t\xi} \right)^D.$$

We deduce from (22), (23), (24) and (26) that the density $g_{Z_n}(t)$ satisfies, for every $t > 0$,

$$(27) \quad g_{Z_n}(t) \leq \frac{\lambda^{2n\beta} \omega_{D-2}^2}{D\mathbb{P}(x \in \mathcal{O}_{n,n})} \int_0^1 \int_0^1 J_n''(x, y, t, s, \xi) ds d\xi$$

where

$$\begin{aligned} J_n''(x, y, t, s, \xi) \\ = e^{-\lambda^{n\beta} \kappa_D \left(\frac{\lambda^{-\frac{n\alpha}{D}} \|x - y\| s}{t\xi} \right)^D} \frac{(\sqrt{2} \lambda^{-\frac{n\alpha}{D}} \|x - y\| s)^{2D}}{t^{2D+1} \xi^D} ((1 - s^2)(1 - \xi^2))^{\frac{D-3}{2}}. \end{aligned}$$

Subcase $D \geq 3$. We then use the change of variables $s = s_\tau = \lambda^{\frac{n\alpha}{D}} \|x - y\|^{-1} t\xi\tau$. Using that $(1 - s^2)(1 - \xi^2)$ and ξ are bounded by 1, we obtain from the change of variables that

$$\begin{aligned} g_{Z_n}(t) &\leq \frac{\lambda^{2n\beta} \omega_{D-2}^2}{D\mathbb{P}(x \in \mathcal{O}_{n,n})} \int_0^1 \int_{\{\tau > 0\}} \tau^D e^{-\lambda^{n\beta} \kappa_D \tau^D} \frac{(2\tau\xi)^D}{t} \frac{t\xi}{\lambda^{-\frac{n\alpha}{D}} \|x - y\|} d\tau d\xi \\ &\leq \frac{C}{\mathbb{P}(x \in \mathcal{O}_{n,n})} \frac{\lambda^{2n\beta + \frac{n\alpha}{D}}}{\|x - y\|} \int_{\{\tau > 0\}} \tau^{2D} e^{-\lambda^{n\beta} \kappa_D \tau^D} d\tau \\ &= \frac{C'}{\mathbb{P}(x \in \mathcal{O}_{n,n})} \frac{\lambda^{-\frac{n(\beta - \alpha)}{D}}}{\|x - y\|} \end{aligned}$$

where C and C' are two positive constants which only depend on D .

Subcase $D = 2$. We return to (27) and apply the same change of variables $s = s_\tau = \lambda^{\frac{n\alpha}{D}} \|x - y\|^{-1} t\xi\tau$. We now obtain that

$$(28) \quad g_{Z_n}(t) \leq \frac{8\lambda^{2n\beta} \lambda^{\frac{n\alpha}{2}}}{\|x - y\| \mathbb{P}(x \in \mathcal{O}_{n,n})} \int_{\{\tau > 0\}} \tau^4 e^{-\lambda^{n\beta} \pi \tau^2} (\dots) d\tau$$

where

$$(\dots) = \int_{\xi=0}^{1 \wedge \frac{\lambda^{-\frac{n\alpha}{2}} \|x - y\|}{t\tau}} (1 - \xi)^{-\frac{1}{2}} \left(1 - \frac{t\xi\tau}{\lambda^{-\frac{n\alpha}{2}} \|x - y\|} \right)^{-\frac{1}{2}} d\xi.$$

We notice that there exists a positive constant $C > 0$ such that for every $a > 0$, we have

$$(29) \quad \int_{\xi=0}^{1 \wedge a} (1 - \xi)^{-\frac{1}{2}} \left(1 - \frac{\xi}{a} \right)^{-\frac{1}{2}} d\xi \leq C |\log |a - 1||.$$

Indeed, due to the facts that the left-hand side of (29) is bounded for large a and that the calculation is symmetric with respect to 1, it is enough to look for the behaviour of the Abelian-type integral when $a > 1$ is close to 1. A direct calculation shows then that

$$\int_0^1 (1-\xi)^{-\frac{1}{2}} \left(1 - \frac{\xi}{a}\right)^{-\frac{1}{2}} d\xi = \sqrt{a} \operatorname{argch} \left(\frac{a+1}{a-1} \right) \underset{a \rightarrow 1}{\sim} -\log(a-1),$$

which proves (29). Consequently, we get from (28) and (29) that

$$g_{Z_n}(t) \leq \frac{C' \lambda^{2n\beta} \lambda^{\frac{n\alpha}{2}}}{\|x-y\| \mathbb{P}(x \in \mathcal{O}_{n,n})} \int_{\{\tau > 0\}} \tau^4 e^{-\lambda^{n\beta} \pi \tau^2} \left| \log \left| 1 - \frac{\lambda^{-\frac{n\alpha}{2}} \|x-y\|}{t\tau} \right| \right| d\tau,$$

where C' denotes again a positive constant.

We now fix $\varepsilon \in (0, 1)$ and we split the integral:

- on the range of τ which satisfies $|1 - \frac{\lambda^{-\frac{n\alpha}{2}} \|x-y\|}{t\tau}| > \varepsilon$, the upper-bound is similar to the case $D \geq 3$;

- on the range of τ satisfying $|1 - \frac{\lambda^{-\frac{n\alpha}{2}} \|x-y\|}{t\tau}| < \varepsilon$, the integral is bounded by

$$\begin{aligned} & \frac{1}{(1-\varepsilon)^6} e^{-\lambda^{n\beta} \pi \frac{\lambda^{-\frac{n\alpha}{2}} \|x-y\|^2}{(1+\varepsilon)^2 t^2}} \left(\frac{\lambda^{-\frac{n\alpha}{2}} \|x-y\|}{t} \right)^5 \int_{u=1-\varepsilon}^{1+\varepsilon} |\log |1-u^{-1}|| du \\ & \leq C' \varphi \left(\frac{\lambda^{-\frac{n\alpha}{2}} \|x-y\|}{t} \right) \end{aligned}$$

where $\varphi(u) = e^{-\lambda^{n\beta} \pi \frac{u^2}{(1+\varepsilon)^2}} u^5$, $u > 0$.

It remains to notice that the maximum of the function φ is of order $O(\lambda^{-\frac{5}{2}n\beta})$ to deduce the required result (15). $\square$

We conclude this subsection with the integrability of the Lipschitz constant $L(x)$ of the affine part of Δ_0 above x , i.e.

$$(30) \quad L(x) = \frac{2}{\|c_0(x) - c'_0(x)\|}.$$

We define the new set $\tilde{\mathcal{O}}_{n,N}$ as

$$\tilde{\mathcal{O}}_{n,N} = \left\{ x \in [0, 1]^D : \text{all points of } B_{\lambda^{\frac{n\beta}{D}} \tau_N}(x) \text{ are in the same simplex of } \mathcal{S}_0 \text{ as } x \right\}.$$

Proposition 1.3. *For every $x \in [0, 1]^D$, $\mathbb{E}(L(x)) < \infty$ and $\sup_{0 \leq n \leq N} \mathbb{E}(L(x) | x \in \tilde{\mathcal{O}}_{n,N}) < \infty$.*

Proof. We could deal with the conditional distribution of $L(x)$ in the same spirit as in the proof of Proposition 1.2. The conditional density of $\|c_0(x) - c'_0(x)\|$ would be in particular very close to (16). For the sake of simplicity, we choose to use a direct argument for removing the conditioning. Indeed, we notice the following fact: on the event $\{x \in \tilde{\mathcal{O}}_{n,N}\}$, a vicinity of x is in the same simplex of $\mathcal{S}_0$ which means that the conditioning favors flatter pyramid faces above x and smaller Lipschitz constants $L(x)$. Consequently, we have $\mathbb{E}(L(x) | x \in \tilde{\mathcal{O}}_{n,N}) \leq \mathbb{E}(L(x))$ for every $n, N \geq 0$.

For $D = 1$, the integrability of the variable $L(x)$ given by (30) comes from the fact that the distance from the two neighbors of x (the nearest and second nearest)

is Gamma-distributed. When $D \geq 2$, we use a reasoning similar to the proof of Proposition 1.2 to obtain that

$$\begin{aligned} \mathbb{E}(L(x)) &= \mathbb{E}\left(\sum_{z_1 \neq z_2} \frac{2}{\|z_1 - z_2\|} \mathbb{1}_{(c_n(x), c'_n(x))}(z_1, z_2)\right) \\ (31) \quad &= \iint \frac{2}{\|z_1 - z_2\|} \mathbb{P}((x + \mathbb{R}_+(x - z_1)) \cap H_{z_1, z_2} \in \mathcal{C}_{z_1} \cap \mathcal{C}_{z_2}) dz_1 dz_2. \end{aligned}$$

We write $z_2 = z_1 + \rho u$ where $u \in \mathbb{S}^{D-1}$, $\rho > 0$ and $u = s \frac{x - z_1}{\|x - z_1\|} + \sqrt{1 - s^2} v$ with $s \in (0, 1)$ and $v \in \mathbb{S}^{D-1} \cap \{x - z_1\}^\perp$. In particular, the distance from z_1 to the point $(x + \mathbb{R}_+(x - z_1)) \cap H_{z_1, z_2}$ is $\frac{\rho}{2s}$. Consequently, we deduce from a change of variables applied to the integral in (31) that

$$\mathbb{E}(L(x)) = \iint \int_{s=0}^1 \frac{2\omega_{D-2}}{\rho} \mathbb{1}_{\mathbb{R}_+}(\rho - 2\|x - z_1\|s) e^{-\kappa_D(\frac{\rho}{2s})^D} \rho^{D-1} (1-s^2)^{\frac{D-3}{2}} ds d\rho dz_1.$$

When $D \geq 3$, we proceed with the change of variables $\tau = \tau_s = \frac{\rho}{2s}$. There is a constant $C > 0$ such that

$$\begin{aligned} \mathbb{E}(L(x)) &\leq \omega_{D-2} \int_{\rho=0}^{\infty} \rho^{D-1} \int_{\tau=\frac{\rho}{2}}^{\infty} \left(\int_{B(x, \tau)} dz_1 \right) e^{-\kappa_D \tau^D} \tau^{-2} d\tau d\rho \\ &\leq C \int_{\rho=0}^{\infty} \rho^{D-1} \int_{\tau=\frac{\rho}{2}}^{\infty} \tau^{D-2} e^{-\kappa_D \tau^D} d\tau d\rho \\ &\leq C \int_{\rho=0}^{\infty} \rho^{D-1} e^{-\frac{\kappa_D}{2}(\frac{\rho}{2})^D} d\rho \int_{\tau=0}^{\infty} \tau^{D-2} e^{-\frac{\kappa_D}{2} \tau^D} d\tau < \infty. \end{aligned}$$

Finally, when $D = 2$, with the same change of variables, we get

$$(32) \quad \mathbb{E}(L(x)) \leq C \int_{\rho=0}^{\infty} \rho \int_{\tau=\frac{\rho}{2}}^{\infty} e^{-\pi \tau^2} \frac{d\tau d\rho}{\sqrt{1 - (\frac{\rho}{2\tau})^2}}.$$

We treat separately the integral in τ for fixed $\rho > 0$:

$$\begin{aligned} \int_{\tau=\frac{\rho}{2}}^{\infty} e^{-\pi \tau^2} \frac{d\tau}{\sqrt{1 - (\frac{\rho}{2\tau})^2}} &\leq 2\rho e^{-\pi(\frac{\rho}{2})^2} \int_{\tau=\frac{\rho}{2}}^{\rho} \frac{\rho}{2\tau^2} \frac{d\tau}{\sqrt{1 - (\frac{\rho}{2\tau})^2}} + \sqrt{\frac{4}{3}} \int_{\tau=\rho}^{\infty} e^{-\pi \tau^2} d\tau \\ &\leq 2\rho e^{-\pi(\frac{\rho}{2})^2} \left[\arccos\left(\frac{\rho}{2u}\right) \right]_{\frac{\rho}{2}}^{\rho} + \sqrt{\frac{4}{3}} e^{-\frac{\pi}{2}\rho^2} \int_{\tau=0}^{\infty} e^{-\frac{\pi}{2}\tau^2} d\tau \\ (33) \quad &\leq \frac{2\pi}{3} \rho e^{-\pi(\frac{\rho}{2})^2} + C' e^{-\frac{\pi}{2}\rho^2}, \end{aligned}$$

where C' is a positive constant. Inserting (33) in (32), we get the required result. $\square$

1.4. Size of the increments of F . The box-dimension of Γ , as well as its Hausdorff dimension, is closely related to the oscillations of F (see [13, 14]). Let us recall that, for every $A \subset [0, 1]^D$, the oscillation of F over A is defined by

$$(34) \quad \text{osc}(F, A) = \sup_{y, y' \in A} |F(y') - F(y)|.$$

In particular, we will consider, for all $x \in [0, 1]^D$ and $\tau > 0$, the oscillation of F over the cube $x + [0, \tau]^D$ given by

$$(35) \quad \text{osc}_\tau(x) = \text{osc}(F, x + [0, \tau]^D) = \sup_{y, y' \in x + [0, \tau]^D} |F(y') - F(y)|.$$

Proposition 1.4. *Let $0 < p < \frac{\alpha}{H}$. Then, for every $x \in [0, 1]^D$, we have, when $N \rightarrow \infty$,*

$$\mathbb{E}(\text{osc}_{\tau_N}(x)) = \mathbb{E}(\text{osc}_{\tau_N}(0)) = O(\tau_N^p).$$

Proof. Let us write

$$\delta_N = \sup_{x \in [0, \tau_N]^D} |F(x) - F(0)| = \sup_{x \in [0, \tau_N]^D} |Z(x, 0)|.$$

We claim that

$$(36) \quad \mathbb{P}(\liminf \{\delta_N \leq \tau_N^p\}) = 1.$$

By Markov's inequality,

$$(37) \quad \mathbb{P}(\delta_N \geq \tau_N^p) \leq \tau_N^{-p} \mathbb{E}(\delta_N).$$

We can write

$$\mathbb{E}(\delta_N) \leq \mathbb{E}\left(\sum_{n=0}^{\infty} \sup_{x \in [0, \tau_N]^D} |Z_n(x, 0)|\right) = S_1(N) + S_2(N) + S_3(N)$$

with

$$\begin{aligned} S_1(N) &= \sum_{n=0}^N \mathbb{E}\left(\sup_{x \in [0, \tau_N]^D} |Z_n(x, 0)| \mid 0 \in \mathcal{O}_{n,N}\right) \mathbb{P}(0 \in \mathcal{O}_{n,N}), \\ S_2(N) &= \sum_{n=0}^N \mathbb{E}\left(\sup_{x \in [0, \tau_N]^D} |Z_n(x, 0)| \mid 0 \notin \mathcal{O}_{n,N}\right) \mathbb{P}(0 \notin \mathcal{O}_{n,N}), \\ S_3(N) &= \sum_{n=N+1}^{\infty} \mathbb{E}\left(\sup_{x \in [0, \tau_N]^D} |Z_n(x, 0)|\right). \end{aligned}$$

Since $[0, \tau_n]^D \subset B_{\sqrt{D}\tau_N}(0)$, we mention that for the purpose of this proof, the definition (7) of the set $\mathcal{O}_{n,N}$ should be slightly adapted by substituting $\sqrt{D}\tau_N$ for τ_N . For the sake of simplicity, we omit that technical detail.

For $S_1(N)$, we notice that

$$\mathbb{E}\left(\sup_{x \in [0, \tau_N]^D} |Z_n(x, 0)| \mid 0 \in \mathcal{O}_{n,N}\right) \leq (\lambda^{-\frac{n\alpha}{D}} \sqrt{D} \tau_N) (\lambda^{\frac{n\beta}{D}} \mathbb{E}(L(0) \mid 0 \in \tilde{\mathcal{O}}_{n,N}))$$

where $L(0)$ is the Lipschitz constant of Δ_0 at 0 when the underlying Poisson point process is homogeneous of intensity 1. Indeed, the function Δ_n is Lipschitz above 0 with Lipschitz constant equal in distribution to $\lambda^{\frac{n\beta}{D}} L(0)$ by scaling invariance. Moreover, the distribution of that Lipschitz constant conditional on $\{0 \in \mathcal{O}_{n,N}\}$ is the same as the distribution of the $\lambda^{\frac{n\beta}{D}} L(0)$ conditional on $\{0 \in \tilde{\mathcal{O}}_{n,N}\}$. Using (5), we get the inequality above. Thanks to Proposition 1.3, we have $\sup_{n,N \in \mathbb{N}} \mathbb{E}(L(0) \mid 0 \in \tilde{\mathcal{O}}_{n,N}) < \infty$.

Thus, using $0 < \alpha \leq \beta \leq 1$, we obtain

$$\begin{aligned} S_1(N) &\leq \sum_{n=0}^N \lambda^{-\frac{n\alpha}{D}} \lambda^{-\frac{NH}{D}} \lambda^{\frac{n\beta}{D}} \sqrt{D} \sup_{n, N \in \mathbb{N}} \mathbb{E}(L(0) | 0 \in \tilde{\mathcal{O}}_{n,N}) \\ &\leq \begin{cases} C_1 \lambda^{\frac{(\beta-\alpha-H)N}{D}} & \text{if } \alpha < \beta, \\ C'_1 N \lambda^{-\frac{NH}{D}} & \text{if } \alpha = \beta, \end{cases} \end{aligned}$$

where C_1, C'_1 are two positive constants which do not depend on N .

For $S_2(N)$ we use the upper estimate (see (5))

$$\mathbb{E} \left(\sup_{x \in [0, \tau_N]^D} |Z_n(x, 0)| \mid 0 \notin \mathcal{O}_{n,N} \right) \leq \lambda^{-\frac{n\alpha}{D}}$$

and Proposition 1.1(i) to get

$$S_2(N) \leq \sum_{n=0}^N \lambda^{-\frac{n\alpha}{D}} \lambda^{\frac{n\beta-NH}{D}} \leq \begin{cases} C_2 \lambda^{\frac{(\beta-\alpha-H)N}{D}} & \text{if } \alpha < \beta, \\ C'_2 N \lambda^{-\frac{NH}{D}} & \text{if } \alpha = \beta, \end{cases}$$

where C_2, C'_2 are two positive constants which do not depend on N .

Finally, for $S_3(N)$ we only use the upper estimate

$$\mathbb{E} \left(\sup_{x \in [0, \tau_N]^D} |Z_n(x, 0)| \right) \leq \lambda^{-\frac{n\alpha}{D}}$$

to get

$$S_3(N) \leq \sum_{n=N+1}^{\infty} \lambda^{-\frac{n\alpha}{D}} \leq C_3 \lambda^{-\frac{N\alpha}{D}}$$

where $C_3 > 0$ is a positive constant which does not depend on N .

Therefore,

$$\mathbb{E} \left(\sum_{n=0}^{\infty} \sup_{x \in [0, \tau_N]^D} |Z_n(x, 0)| \right) \leq \begin{cases} C(\tau_N^{1-\frac{\beta-\alpha}{H}} + \tau_N^{\frac{\alpha}{H}}) & \text{if } \alpha < \beta, \\ C'(|\log(\tau_N)|\tau_N + \tau_N^{\frac{\alpha}{H}}) & \text{if } \alpha = \beta, \end{cases}$$

where C, C' are two positive constants which do not depend on N . The rhs of (37) is in particular summable in N as soon as $p < \frac{\alpha}{H}$ (which guarantees that $1 - \frac{\beta-\alpha}{H} > p$ since $1 - \frac{\beta}{H} > 0$). Consequently, by Borel-Cantelli's lemma, (36) holds. Then, we obtain

$$\text{osc}_{\tau_N}(0) \leq 2\delta_N = O(\tau_N^p)$$

almost surely for all N large enough. To conclude, let us notice that, by stationarity, it follows that

$$\mathbb{E}(\text{osc}_{\tau_N}(x)) = \mathbb{E}(\text{osc}_{\tau_N}(0)) = O(\tau_N^p)$$

for all $x \in [0, 1]^D$. □

We conclude this subsection with an estimate of the expectation of a particular functional of the increment $F(x) - F(y)$ that will appear in the application of a Frostman-type lemma in the next section.

Proposition 1.5. *Let $s > 1$ and $n \geq 0$. If $x, y \in [0, 1]^D$ satisfy $\tau_{n+1} < \|x - y\| \leq \tau_n$, then*

$$(38) \quad \mathbb{E} \left((|F(x) - F(y)|^2 + \|x - y\|^2)^{-\frac{s}{2}} \mathbb{1}_{\mathcal{O}_{n,n}}(x) \right) \leq C \|x - y\|^{-s + \frac{\beta - \alpha}{H}}$$

where $C > 0$ is a constant which does not depend on x, y, n .

Proof. Remember that $F(x) - F(y) = Z_n(x, y) + S_n(x, y)$ where $Z_n(x, y)$ and $S_n(x, y)$ are independent. Let $\mathbb{P}_n$ be the probability associated with $\mathcal{X}_n$, and let μ_{S_n} be the probability distribution of the random variable $S_n(x, y)$. From Proposition 1.2 one obtains

$$\begin{aligned} & \mathbb{E} \left((|F(x) - F(y)|^2 + \|x - y\|^2)^{-\frac{s}{2}} \mathbb{1}_{\mathcal{O}_{n,n}}(x) \right) \\ &= \iint ((Z_n(x, y) + v)^2 + \|x - y\|^2)^{-\frac{s}{2}} \mathbb{1}_{\mathcal{O}_{n,n}}(x) d\mathbb{P}_n d\mu_{S_n}(v) \\ &= \iint \mathbb{P}(x \in \mathcal{O}_{n,n}) ((u + v)^2 + \|x - y\|^2)^{-\frac{s}{2}} g_{Z_n}(u) du d\mu_{S_n}(v) \\ &\leq \int \mathbb{P}(x \in \mathcal{O}_{n,n}) \left(\int_{\{|u+v| < \|x-y\|\}} \|x - y\|^{-s} g_{Z_n}(u) du d\mu_{S_n}(v) \right. \\ &\quad \left. + \int_{\{|u+v| > \|x-y\|\}} |u + v|^{-s} g_{Z_n}(u) du d\mu_{S_n}(v) \right) \\ &\leq 2 \|x - y\| \sup_{t \in \mathbb{R}} (g_{Z_n}(t)) \|x - y\|^{-s} + \sup_{t \in \mathbb{R}} (g_{Z_n}(t)) \int_{\{|u+v| > \|x-y\|\}} |u + v|^{-s} du d\mu_{S_n}(v) \\ &\leq 2C \|x - y\| \|x - y\|^{-1} \lambda^{-\frac{n(\beta - \alpha)}{D}} \|x - y\|^{-s} + C \|x - y\|^{-1} \lambda^{-\frac{n(\beta - \alpha)}{D}} \|x - y\|^{-s+1} \\ &= C \|x - y\|^{-s} \lambda^{-\frac{n(\beta - \alpha)}{D}}. \end{aligned}$$

Finally, the assumption on $\|x - y\|$ implies that $\lambda^{-n} \leq (\|x - y\| \lambda^{\frac{H}{D}})^{\frac{D}{H}}$, which provides the desired bound. $\square$

2. PROOF OF THE MAIN THEOREM

Let us recall that for any non-empty compact set $K \subset \mathbb{R}^{D+1}$ one has (see [14])

$$(39) \quad 0 \leq \dim_H(K) \leq \dim_B(K) \leq D + 1.$$

Thus the proof of Theorem 1 will consist in proving that $D + 1 - \frac{\alpha}{\beta}$ is an upper bound for $\dim_B(\Gamma)$ and a lower bound for $\dim_H(\Gamma)$.

2.1. An upper bound for the box-dimension of Γ . First we investigate the box-dimension of Γ . For every $\tau > 0$ we cover $[0, 1]^D \times \mathbb{R}$ with τ -mesh cubes and denote by $\mathcal{N}(\tau)$ the (finite) number of cubes from this partition which intersect Γ . Then, we can express the box-dimension of Γ in terms of $\mathcal{N}(\tau_N)$ (see Section 3.1 in [14] and Section 2.2 in [38]):

$$(40) \quad \dim_B(\Gamma) = \limsup_{N \rightarrow \infty} \frac{\log \mathcal{N}(\tau_N)}{|\log(\tau_N)|}.$$

Lemma 2.1. *There exists a constant $d > 0$ such that $\mathbb{P}(\dim_B(\Gamma) = d) = 1$.*

Proof. For every $m \in \mathbb{N}$, let us denote by $\mathcal{A}_m$ the σ -algebra generated by the point process $\mathcal{X}_m$ and $F_m(x) = \sum_{n=0}^m \lambda^{-\frac{n\alpha}{D}} \Delta_n(x)$, $x \in [0, 1]^D$. Since F_m is a Lipschitz function, the graph of the function $F - F_m$ has the same box-dimension as the graph of F (see Section 12.4 in [38] or Chapter 11 in [14]). Consequently, we can use (40)

to show that $\dim_B(\Gamma)$ is a random variable which is measurable with respect to $\sigma(\mathcal{A}_m : m \geq n)$ for every $n \in \mathbb{N}$. We then use the 0-1 law to deduce that it is almost surely constant. $\square$

Proof of the upper bound of (4). Let $(\tau_{N_k})_k$ be a subsequence of $(\tau_N)_N$ such that

$$\dim_B(\Gamma) = \lim_{k \rightarrow \infty} \frac{\log \mathcal{N}(\tau_{N_k})}{|\log(\tau_{N_k})|} \leq D + 1.$$

Applying Lebesgue's convergence theorem we obtain

$$\mathbb{E} \left(\lim_{k \rightarrow \infty} \frac{\log \mathcal{N}(\tau_{N_k})}{|\log(\tau_{N_k})|} \right) = \lim_{k \rightarrow \infty} \mathbb{E} \left(\frac{\log \mathcal{N}(\tau_{N_k})}{|\log(\tau_{N_k})|} \right) \leq \limsup_{N \rightarrow \infty} \mathbb{E} \left(\frac{\log \mathcal{N}(\tau_N)}{|\log(\tau_N)|} \right).$$

Then, Jensen's inequality with the concave function $\log$ yields

$$\mathbb{E}(\dim_B(\Gamma)) \leq \limsup_{N \rightarrow \infty} \mathbb{E} \left(\frac{\log \mathcal{N}(\tau_N)}{|\log(\tau_N)|} \right) \leq \limsup_{N \rightarrow \infty} \log \mathbb{E} \left(\frac{\mathcal{N}(\tau_N)}{|\log(\tau_N)|} \right).$$

We now use Proposition 11.1 from [14] and Proposition 1.4 to get

$$\mathbb{E}(\mathcal{N}(\tau_N)) \leq 2 \lceil \tau_N^{-1} \rceil^D + \tau_N^{-1} \sum_{\substack{k=(k_1, \dots, k_D) \\ 0 \leq k_i \leq \lceil \tau_N^{-1} \rceil}} \mathbb{E}(\text{osc}_{\tau_N}(k\tau_N)) = O(\tau_N^{p-D-1}).$$

In conclusion, for every $H > \beta$ and $p < \frac{\alpha}{H}$, we obtain $\mathbb{E}(\dim_B(\Gamma)) \leq D + 1 - p$. We finally get

$$\dim_B(\Gamma) = \mathbb{E}(\dim_B(\Gamma)) \leq D + 1 - \frac{\alpha}{\beta}$$

by letting $H \rightarrow \beta$, $p \rightarrow \frac{\alpha}{\beta}$, and by using Lemma 2.1. $\square$

2.2. A lower bound for the Hausdorff dimension of Γ . To find a lower bound for the Hausdorff dimension of a compact set is generally a difficult problem. An important step was made in [19] when Hunt proposed a way to find a lower bound for the Hausdorff dimension of the graph of Weierstrass functions using the 'finite energy criterion'. The arguments of [19] can be applied for a large class of Weierstrass-type functions, but not for the Takagi-Knopp series defined by (1) because the sawtooth function Δ is not regular enough. This well-known criterion is used for calculating the Hausdorff dimension of more general fractal sets (see e.g. Chapter 4 in [31]).

Let us recall that the Hausdorff dimension of a non-empty compact set $K \subset \mathbb{R}^{D+1}$ may be expressed in terms of finite energy of some measures thanks to a lemma due to Frostman (see e.g. [21, 27]):

$$\dim_H(K) = \sup_{\mu} \left(\sup \{s \geq 0 : I_s(\mu) < \infty\} \right)$$

where the supremum on μ is taken over all the finite and non-null Borel measures such that $\mu(K) > 0$ and $I_s(\mu)$ is the s -energy of μ defined by

$$(41) \quad I_s(\mu) = \iint \|x - y\|^{-s} d\mu(x) d\mu(y).$$

Therefore, if such a measure μ satisfies $I_s(\mu) < \infty$, then $\dim_H(K) \geq s$.

Let us recall now a classical way to construct such a measure on Γ . For each $N \geq 0$ the set W_N (see (8)) is a Borel subset of $[0, 1]^D$. Since F is a continuous function, then Γ is a Borel set too so that we can consider the measure μ_{W_N} obtained

by lifting onto Γ the D -dimensional Lebesgue measure restricted to W_N . Precisely, for all Borel sets $E \subset \mathbb{R}^{D+1} = \mathbb{R}^D \times \mathbb{R}$,

$$\mu_{W_N}(E) = \text{Vol}\{x \in [0, 1]^D \cap W_N \text{ such that } (x, F(x)) \in E\}$$

and μ_{W_N} is a positive measure as soon as $\text{Vol}(W_N) > 0$. The s -energy of μ_{W_N} is then

$$(42) \quad I_s(\mu_{W_N}) = \iint_{W_N \times W_N} (\|x - y\|^2 + |F(x) - F(y)|^2)^{-\frac{s}{2}} dx dy.$$

Notice that the finiteness of $I_s(\mu_{W_N})$ depends only on the size of the increments $F(x) - F(y)$ when $\|x - y\|$ is small.

Proof of the lower bound of (4). Let us consider, for all $n \geq 0$, the set

$$T_n = \{(x, y) \in [0, 1]^D \times [0, 1]^D : \tau_{n+1} < \|x - y\| \leq \tau_n\}.$$

Let $N \geq 1$ and $s > 1$. Since $W_N \subset \mathcal{O}_{n,n}$ for all $n \geq N$, we have, with (42),

$$\begin{aligned} I_s(\mu_{W_N}) &\leq \iint_{(x,y) \in W_N \times [0,1]^D} (\|x - y\|^2 + |F(x) - F(y)|^2)^{-\frac{s}{2}} dx dy \\ &\leq C' + C_N + \sum_{n=N}^{\infty} \iint_{(x,y) \in T_n \cap (W_N \times [0,1]^D)} (\|x - y\|^2 + |F(x) - F(y)|^2)^{-\frac{s}{2}} dx dy \\ &\leq C' + C_N + \sum_{n=N}^{\infty} \iint_{(x,y) \in T_n} (\|x - y\|^2 + |F(x) - F(y)|^2)^{-\frac{s}{2}} \mathbb{1}_{\mathcal{O}_{n,n}}(x) dx dy \end{aligned}$$

where

$$\begin{aligned} C' &= \iint_{\{(x,y) \in W_N \times [0,1]^D : \|x-y\| \geq 1\}} (\|x - y\|^2 + |F(x) - F(y)|^2)^{-\frac{s}{2}} dx dy \\ &\leq \iint_{\{(x,y) \in [0,1]^D \times [0,1]^D : \|x-y\| \geq 1\}} \|x - y\|^{-s} dx dy \leq 1 \end{aligned}$$

and

$$\begin{aligned} C_N &= \iint_{(x,y) \in (T_0 \cup \dots \cup T_{N-1}) \cap (W_N \times [0,1]^D)} (\|x - y\|^2 + |F(x) - F(y)|^2)^{-\frac{s}{2}} dx dy \\ &\leq \iint_{(x,y) \in (T_0 \cup \dots \cup T_{N-1})} \|x - y\|^{-s} dx dy \leq \lambda^{N H s}. \end{aligned}$$

To show that the integral (42) is finite almost surely it is enough to show that its expectation is finite. By Fubini's theorem,

$$\begin{aligned} \mathbb{E}(I_s(\mu_{W_N})) &\leq 1 + \lambda^{N H s} \\ &\quad + \sum_{n=N}^{\infty} \iint_{(x,y) \in T_n} \mathbb{E}((\|x - y\|^2 + |F(x) - F(y)|^2)^{-\frac{s}{2}} \mathbb{1}_{\mathcal{O}_{n,n}}(x)) dx dy. \end{aligned}$$

Using the estimate (38) we obtain

$$\mathbb{E}(I_s(\mu_{W_N})) \leq 1 + \lambda^{N H s} + C \iint_{(x,y) \in \bigcup_{n=N}^{\infty} T_n} \|x - y\|^{-s + \frac{\beta - \alpha}{H}} dx dy.$$

This latter integral converges as soon as $-s + \frac{\beta - \alpha}{H} > -D$. Therefore the random measure μ_{W_N} has a finite s -energy for all $1 < s < D + \frac{\beta - \alpha}{H}$. Since N may be

chosen such that the probability $\mathbb{P}(\text{Vol}(W_N) > 0)$ will be arbitrarily close to 1 (see Proposition 1.1) we deduce that

$$\dim_{\text{H}}(\Gamma) \geq D + \frac{\beta - \alpha}{H}$$

for all $H > \beta$ and almost surely. We obtain the desired lower bound by letting $H \in \mathbb{Q}_+$ go to β . $\square$

3. RELATED MODELS

In this section, we study the fractal properties of two different models which are related to our Poisson-Voronoi construction: a deterministic series of pyramidal functions with hexagonal bases on the one hand, and a random perturbation of the classical Takagi-Knopp series on a dyadic mesh on the other hand.

3.1. Takagi-like series directed by hexagonal Voronoi tessellations. The series that we study here is only defined in $\mathbb{R}^2$. It is very close to the original function $F_{\lambda, \alpha, \beta}$. The novelty lies in the Δ_n functions: we consider now pyramids with a regular hexagonal basis. This model is naturally related to the previous one for two reasons. First, a hexagonal mesh is known to be the Voronoi tessellation generated by a regular triangular mesh. Second, the mean of the number of vertices of a typical cell from a Poisson-Voronoi tessellation is known to be 6 (see e.g. Prop. 3.3.1 in [30]) so that a hexagonal mesh may be seen as an *idealized* realization of a Poisson-Voronoi tessellation.

We start with the deterministic Voronoi tessellation whose cells are identical regular hexagons such that one is centered at the origin $(0, 0)$ and has a vertex at $(1, 0)$. Then, considering all the centers of these hexagons as a set of points $\mathcal{X}_0$, we set $\mathcal{X}_n = 2^{-n}\mathcal{X}_0$ and construct the associated hexagonal Voronoi tessellation. Here again $\Delta_n : \mathbb{R}^2 \rightarrow [0, 1]$ is the piecewise linear pyramidal function satisfying $\Delta_n = 0$ on $\bigcup_{c \in \mathcal{X}_n} \partial \mathcal{C}_c$ and $\Delta_n = 1$ on $\mathcal{X}_n$.

Let us notice that, for all $x \in \mathbb{R}^2$ and all $n \geq 0$, we have $\Delta_n(x) = \Delta(2^n x)$. We fix $\alpha \in (0, 1]$ and define a function

$$(43) \quad f_\alpha(x) = \sum_{n=0}^{\infty} 2^{-n\alpha} \Delta_n(x) = \sum_{n=0}^{\infty} 2^{-n\alpha} \Delta(2^n x), \quad x \in \mathbb{R}^2.$$

The main theorem of this section is the analogue of Theorem 1. Actually we state a more precise result than Proposition 1.4 for the oscillations of f_α but we cannot determine the Hausdorff dimension of Γ_α .

Theorem 3.1. *Let $0 < \alpha \leq 1$. Then f_α is a continuous function such that*

$$(44) \quad \exists C, C' > 0, \quad \forall \tau \in (0, 1), \quad \forall x \in [0, 1]^2, \quad C' \tau^\alpha \leq \text{osc}_\tau(x) \leq C \tau^\alpha.$$

Moreover, its graph

$$\Gamma_\alpha = \{(x, f_\alpha(x)) : x \in [0, 1]^2\} \subset \mathbb{R}^2 \times \mathbb{R}$$

is a fractal set satisfying

$$(45) \quad \dim_{\text{B}}(\Gamma_\alpha) = 3 - \alpha.$$

Proof. In the sequel we again drop the index α so that $f = f_\alpha$ and $\Gamma = \Gamma_\alpha$. We also keep the notation $Z_n(x, y) = 2^{-n\alpha}(\Delta_n(x) - \Delta_n(y)) = 2^{-n\alpha}(\Delta(2^n x) - \Delta(2^n y))$ for all $x, y \in \mathbb{R}^2$.

(i) Let us state the upper estimates first. We fix $x, y \in [0, 1]^2$ such that $\|x - y\| \in (0, 1)$ and consider $N \geq 1$ such that $2^{-N} < \|x - y\| \leq 2^{-(N-1)}$. Using the fact that Δ is Lipschitz, with Lipschitz constant 1, and bounded by 1, we have $|Z_n(x, y)| \leq 2^{-n\alpha} \min(2^n \|x - y\|, 1)$. Therefore

$$\begin{aligned} |f(x) - f(y)| &\leq \sum_{n=0}^{\infty} |Z_n(x, y)| \leq \sum_{n=0}^{N-1} (2^{n(1-\alpha)} \|x - y\|) + \sum_{n=N}^{\infty} 2^{-n\alpha} \\ &\leq \|x - y\| \frac{2^{N(1-\alpha)}}{2^{1-\alpha} - 1} + \frac{2^{-N\alpha}}{1 - 2^{-\alpha}} \\ &\leq \|x - y\| \frac{(2\|x - y\|^{-1})^{(1-\alpha)}}{2^{1-\alpha} - 1} + \frac{\|x - y\|^\alpha}{1 - 2^{-\alpha}} \\ &\leq C \|x - y\|^\alpha \end{aligned}$$

where C is a positive constant which only depends on α . Then, $|f(x) - f(y)| \leq C\tau^\alpha$ for all $x, y \in \mathbb{R}^2$ such that $0 < \|x - y\| < \sqrt{2}\tau < 1$. This gives the upper bound in (44).

(ii) Now we state the lower estimates. We begin by finding a lower bound for the oscillation over a hexagonal cell. The key point for estimating this oscillation is to calculate two particular increments for two pairs of well-chosen points belonging to the cell, namely the center and the vertices. To keep in mind the number of the generation, we denote by $\mathcal{C}_c^n$, $c \in \mathcal{X}_n$ (resp. $\mathcal{T}_n$, $\mathcal{S}_n$ and Sk_n), the cells of the Voronoi tessellation of generation n (resp. the set $\{\mathcal{C}_c^n : c \in \mathcal{X}_n\}$, the associated simplex tessellation and the skeleton of the simplex tessellation). Moreover, the six vertices of a cell $\mathcal{C}_c^n$ are denoted by c_i with $i \in \{1, \dots, 6\}$.

Then, let $N \geq 1$, $c \in \mathcal{X}_N$, $c_1, \dots, c_6$ be the vertices of $\mathcal{C}_c^N$ and $i \in \{1, \dots, 6\}$. We can write

$$f(c) - f(c_i) = \sum_{n=0}^{N-1} Z_n(c, c_i) + \sum_{n=N}^{\infty} Z_n(c, c_i).$$

As soon as a point is the center (resp. a vertex) of a cell $\mathcal{C}_c^N$, then it is the center (resp. a vertex) of all the cells of higher generations. Hence $\Delta(2^n c) = 1$ and $\Delta(2^n c_i) = 0$ for all $n \geq N$. Therefore

$$\sum_{n=N}^{\infty} Z_n(c, c_i) = \sum_{n=N}^{\infty} 2^{-n\alpha} = \frac{1}{1 - 2^{-\alpha}} 2^{-N\alpha}.$$

Let $i, j \in \{1, \dots, 6\}$. We obtain

$$\begin{aligned} \sup_{y, y' \in \mathcal{C}_c^N} |f(y') - f(y)| &\geq \frac{1}{2} ((f(c) - f(c_i)) + (f(c) - f(c_j))) \\ (46) \quad &\geq \frac{1}{2} \left(\sum_{n=0}^{N-1} Z_n(c, c_i) + \sum_{n=0}^{N-1} Z_n(c, c_j) \right) + \frac{1}{1 - 2^{-\alpha}} 2^{-N\alpha}. \end{aligned}$$

For a fixed hexagon $\mathcal{C}_c^N$, we claim that there exists a pair of two diametrically opposed vertices c_i and c_j such that the sum of the first two sums above is positive. Indeed, for $n < N$, the center c is included in one or two cells $\mathcal{C}_c^n$ of the tessellation of generation n and it can be only in three positions: at the center c' of a cell from $\mathcal{T}_n$, on one 'edge' of the skeleton Sk_n (i.e. a segment between two consecutive vertices c'_i and c'_{i+1} or between the center c' and one of its vertex c'_i), or on a 'face' (i.e. an open triangle of vertices c' , c'_i and c'_{i+1} or equivalently, a connected component of

the complementary set of Sk_n). Let us denote by C , E and F respectively these three positions of c . We are interested in the behaviour of the sequence of the positions of c when n goes from N to 0. In particular, we notice the two following facts:

- The set of centers of $\mathcal{T}_{n-1}$ is included in the set of centers of $\mathcal{T}_n$. Consequently, if c is in position E or F at step n , it cannot be in position C at step $(n-1)$.
- The skeleton Sk_{n-1} is included in the skeleton Sk_n . Consequently, if c is in position F at step n , it cannot be in position E at step $(n-1)$.

Consequently, the sequence of positions when n goes from N to 0 has to be $(C, \dots, C)$ or $(C, \dots, C, E, \dots, E)$ or $(C, C, \dots, C, E, \dots, E, F, \dots, F)$ (see the first generations in Figure 7).

FIGURE 7. The only three possibilities for the sequence of the positions of the centers of the cells. On the left p goes from 1 to 0: c gives (C, C) , c' gives (C, E) and c'' gives (C, E) . On the right p goes from 2 to 0: c gives (C, C, C) , c' gives (C, C, E) , c'' gives (C, E, E) and c''' gives (C, E, F) .

Let us choose now the pair (c_i, c_j) of vertices from $\mathcal{C}_c^N$ which satisfies that the sum of the first two sums in (46) is non-negative. In the sequel, we will use the following general facts:

- When c is in position E at step n , then there exist exactly two diametrically opposed vertices from $\mathcal{C}_c^N$ which are on the same edge of Sk_n as c .
- When c is in position F at step n , then the whole cell $\mathcal{C}_c^N$ is included in the same face as c .

Case $(C, \dots, C)$. When the sequence of positions of c is $(C, \dots, C)$, we have $\Delta(2^n c) = 1 \geq \Delta(2^n c_i)$ for every $n < N$. Consequently, for any choice of c_i and c_j , the sum of the two sums is non-negative.

Case $(C, \dots, C, E, \dots, E)$. Let n_0 be the maximal $n < N$ such that c is in position E at step n . Let c_i and c_j be the two diametrically opposed vertices associated with c which are on the same edge of the skeleton Sk_{n_0} . For every $n_0 < n < N$, we have $Z_n(c, c_i) \geq 0$ and $Z_n(c, c_j) \geq 0$ (see the previous case). If $n \leq n_0$, either the edge of Sk_n containing c , c_i and c_j is an edge from a hexagon of $\mathcal{T}_n$ or it is a segment between a center of a hexagon and one of its vertices. In the first case, we have $\Delta(2^n c) = \Delta(2^n c_i) = \Delta(2^n c_j) = 0$. In the second case, since c is the midpoint of $[c_i, c_j]$ and the slope of the pyramid is the same above the three

points, we have $\Delta(2^n c) - \Delta(2^n c_i) = -(\Delta(2^n c) - \Delta(2^n c_j))$. Consequently, the sum of the two sums in (46) is non-negative.

Case $(C, C, \dots, C, E, \dots, E, F, \dots, F)$. We define c_i and c_j as in the previous case. The same reasoning as before can be applied for every $n < N$ such that c is in position C or E at step n . Let $n < N$ be such that c is in position F at step n . Then the slope above the three points c , c_i and c_j is constant so the equality $\Delta(2^n c) - \Delta(2^n c_i) = -(\Delta(2^n c) - \Delta(2^n c_j))$ is still valid. Consequently, the sum of the two sums in (46) is non-negative.

Therefore,

$$\sup_{y, y' \in \mathcal{C}_c^N} |F(y') - F(y)| \geq C' 2^{-N\alpha}$$

where C' is a positive constant which only depends on α .

Finally, let $\tau \in (0, 1)$, $x \in [0, 1]^2$ and $N \geq 1$ such that $2^{-N} < \tau \leq 2^{-(N-1)}$. The ball $B_\tau(x)$ contains a cell $\mathcal{C}_c^{N+1}$ of generation $N + 1$, thus

$$\text{osc}_\tau(x) \geq \sup_{y, y' \in \mathcal{C}_c^{N+1}} |F(y') - F(y)| \geq C' 2^{-(N+1)\alpha} \geq C'' \tau^\alpha,$$

which gives the lower bound in (44).

Combining (i) and Proposition 11.1 in [14] (see also [13]) we get $\mathcal{N}(\tau_N) \sim \tau_N^{\alpha-3}$ as $N \rightarrow \infty$. The result is then a consequence of (40). $\square$

3.2. Takagi-Knopp series generated by a random perturbation of the dyadic mesh. In this subsection, we stray from the Voronoi partition of $\mathbb{R}^D$. An alternative way of randomizing the underlying partition of a Takagi-Knopp series is the following: the sequence of dyadic meshes $\mathcal{D}_n = 2^{-n}\mathbb{Z}^D$, $n \in \mathbb{N}$, is kept but each mesh $\mathcal{D}_n$ is translated by a random uniform vector in $2^{-n}(0, 1)^D$. In each cube $C_{n,k}$, $k \in \mathbb{N}$, of the translate of $\mathcal{D}_n$, a random uniform ‘nucleus’ $c_{n,k}$ is chosen independently. The associated random pyramidal function Δ_n is defined so that it is equal to zero on the translate of $\mathcal{D}_n$ and to 1 on the set $\{c_{n,k}, k \in \mathbb{N}\}$. The Takagi-Knopp type series $F_{\alpha,\beta}$, $\alpha, \beta > 0$, is then given by a definition very similar to (3) with $\lambda = 2$. Compared to our Poisson-Voronoi construction, the main advantage of this model is that it preserves the cube structure so that it could be easier to deal with in dimension two for an applicational purpose in image analysis and pixel representation. The essential drawback is that the rigid structure of the mesh prevents us from obtaining an explicit Hausdorff dimension. Still, some results close to those proved in section 1 can be deduced from similar methods. Indeed, if the random oscillation set $\mathcal{O}_{n,N}$, $n, N \in \mathbb{N}$, the increment $Z_n(x, y)$, $x, y \in \mathbb{R}^D$, the density g_{Z_n} of $Z_n(x, y)$ conditionally on $\{x \in \mathcal{O}_{n,N}\}$ and the Lipschitz constant $L(x)$ are defined analogously, then the conclusions of Propositions 1.1 and 1.3 are satisfied. Moreover, point (ii) of Proposition 1.2 is replaced by the following estimate:

$$(47) \quad \sup_{t \in \mathbb{R}} g_{Z_n}(t) \leq \frac{C}{\mathbb{P}(x \in \mathcal{O}_{n,n})} \lambda^{-\frac{n(\beta-\alpha)}{D}} \sum_{i=1}^D \frac{1}{|x_i - y_i|}.$$

As a consequence, it is possible to derive an analogue of Proposition 1.4 and of the upper-bound of the box-dimension in (4). This upper-bound is in particular the exact Hausdorff dimension when $D = 1$. Indeed, in the linear case, the estimate of $\sup_{t \in \mathbb{R}} g_{Z_n}(t)$ in (47) coincides with (ii) of Proposition 1.2, which implies that the lower-bound can be obtained along the same lines as in section 2. We sum up our results in the next proposition, given without a detailed proof.

Proposition 3.2. *Let $F_{\alpha,\beta}$ be the function as above with $0 < \alpha \leq \beta \leq 1$. Then, its graph $\Gamma_{\alpha,\beta}$ satisfies almost surely the following estimates:*

- (i) *For every $D \geq 2$, $\dim_{\text{B}}(\Gamma_{\alpha,\beta}) \leq D + 1 - \frac{\alpha}{\beta}$.*
- (ii) *When $D = 1$, $\dim_{\text{B}}(\Gamma_{\alpha,\beta}) = \dim_{\text{H}}(\Gamma_{\alpha,\beta}) = 2 - \frac{\alpha}{\beta}$.*

Unfortunately, the fact that the sum $\sum_{i=1}^D \frac{1}{|x_i - y_i|}$ is a substitute for the inverse of the Euclidean norm $\|x - y\|^{-1}$ in the estimate (47) makes the proof of the lower-bound of the Hausdorff dimension more intricate for $D \geq 2$. This could be eventually considered as an extra argument in favor of our Poisson-Voronoi construction.

ACKNOWLEDGEMENT

We thank an anonymous referee for a careful reading of the original manuscript, resulting in an improved and more accurate exposition.
